## Supplementary information

Colloidal silica nanomaterials reduce the toxicity of pesticides to algae, depending

## on charge and surface area

Figure S1. Plate design for single exposures. Concentrations are labelled C1-C10 (yellow background) and negative controls are labelled K1-K10 (green background).

Figure S2. Plate design for mixture exposures. Mixture concentrations are labelled C1-3+ECx, positive controls are labeled ECx, nanomaterial controls are labelled C1-C3 and negative controls are labelled K1-K10. All wells containing a treatment are marked yellow while negative controls are marked with green colour.

Figure S3: Concentration-response curve for R. subcapitata after 72h exposure to PQ (A), PCP (B) and DFF (C). The boxes show the inhibition (median, lower/upper quartile, and lower/upper extreme) at the tested concentration and the dotted line shows the fitted curve calculated from a two-parametric concentration-response model. The box shown in black colour (first box from the left) represents the unexposed control.

Figure S4: Absorbed light (%) at excitation/emission wavelengths 425/680 for the different silica nanoparticles, weakly anionic (A), cationic (B), strongly anionic (C) and anionic strongly elongated (D).

Table S1. Size and ZP of silica nanomaterials individually and in mixture with PQ, PCP and DFF in MBL medium at the start and end (t0-t72h). Nanomaterial size was derived from the particle size distributions from the DLS measurements. The size corresponds to the nanomaterial population with the largest volume in percent (% volume), i.e. the largest peak (peak 1) in the size distribution by volume. Samples not measurable, i.e. the DLS could not detect any nanomaterial (due to sedimentation) are presented with N.M.
