## 1 Newns-Anderson model ${ }^{1,2}$

To explain the interfacial coupling, Newns-Anderson approach was employed to compute the hybridization of the highest occupied molecular orbital (HOMO) on ionic liquid with the manifold occupied orbitals on PEDOT. Accordingly, this hybridization possesses a Lorentzian distribution:

$$
\rho(E)=\frac{1}{\left(\varepsilon_{i}-E_{\mathrm{H}(\mathrm{LL}}\right)^{2}+\left(\frac{\mathrm{h} \Gamma}{2}\right)^{2}}
$$

where $\varepsilon_{i}, E_{\mathrm{H}(\mathrm{IL})}$, and $\hbar \Gamma$ in denominator separately describes $i$ th molecular orbital (MO) energy in the IL-PEDOT complexes, the HOMO energy of IL after coupling with PEDOT, and the broadening width taken as the mean deviation of the HOMO levels of IL and it can be viewed as a critical item to illustrate the hybridization quantitatively. Accordingly, the $E_{\mathrm{H}(\mathrm{LL})}$ and $\hbar \Gamma$ are defined as follows: ${ }^{2}$

$$
\begin{gathered}
E_{\mathrm{H}(\mathrm{LL})}=\sum_{i} p_{i} \varepsilon_{i} \\
\mathrm{~h} \Gamma=\sum_{i} p_{i}\left|\varepsilon_{i}-E_{\mathrm{H}(\mathrm{LL})}\right|
\end{gathered}
$$

where $p_{\mathrm{i}}$ is the portion of $i$ th MO for IL, and it is evaluated by:

$$
p_{i}=\frac{\sum_{j}^{\mathrm{A} \in \mathrm{~L}}\left(c_{i j}^{A}\right)^{2}}{\sum_{j}^{\mathrm{A} \in \mathrm{~L}-\mathrm{PEDOT}}\left(c_{i j}^{A}\right)^{2}}
$$

## The calculation of reorganization energy ( $\lambda$ )

The reorganization energy $(\lambda)$ is related to the energy change with the geometry relaxation during charge transport, which can be evaluated by the adiabatic potential energy surface method (the four-point method) and normal mode analysis. The former is expressed as: ${ }^{3}$

$$
\lambda=\lambda_{1}+\lambda_{2}=\left(E_{+}{ }^{0}-E_{0}\right)+\left(E_{0}{ }^{+}-E_{+}^{+}\right)
$$

where $E_{+}{ }^{0}$ is the energy of the neutral molecule calculated on top of the optimized cationic state, $E_{0}$ is the energy of the optimized neutral molecule at ground state, $E_{0}{ }^{+}$is the energy of the cation calculated on top of the optimized neutral state, and $E_{+}^{+}$is the energy of the optimized cation, respectively.

And the normal mode analysis assigns the $\lambda$ to the contribution from each vibrational mode: ${ }^{4}$

$$
\lambda=\lambda_{1}+\lambda_{2}=\sum_{i} \lambda_{1 i}+\sum_{j} \lambda_{2 j}=\sum_{i} \frac{1}{2} \omega_{i} \Delta Q_{i}^{2}+\sum_{j} \frac{1}{2} \omega_{j} \Delta Q_{j}^{2}
$$

where $\lambda_{1 i}$ and $\lambda_{2 j}$ stand for the contributions to the $\lambda$ from vibrational modes $i$ and $j$ of the neutral and cationic geometries separately, $\omega_{i}$ and $\omega_{j}$ represent for the vibrational frequencies of modes $i$ and $j$, and $\Delta Q_{i}$ and $\Delta Q_{j}$ are the displacements along the $i$ th and $j$ th mode coordinates between the equilibrium positions of neutral and cationic states, respectively. By contrast to the $V_{i j}$, a minimized $\lambda$ potentially ensures a large $k_{i j}$. And in this work, we used these two methods to calculate $\lambda$ separately.

## The calculation of hole mobility

The hole mobility ( $\mu$ ) can be obtained based on the non-adiabatic Marcus charge transfer theory: ${ }^{5-7}$

$$
k_{n}=\frac{2 \pi}{\mathrm{~h}}\left|V_{i j}\right|^{2} \sqrt{\frac{1}{4 \pi k_{\mathrm{B}} \mathrm{~T} \lambda}} \exp \left[-\frac{\left(\Delta G_{i j}+\lambda\right)^{2}}{4 \lambda k_{\mathrm{B}} \mathrm{~T}}\right]
$$

where $\hbar$ is reduced Planck's constant, $V_{i j}$ is the transfer integral, $k_{\mathrm{B}}$ is Boltzmann's constant, T is temperature in Kelvin, $\lambda$ is the reorganization energy, and $\Delta G_{i j}$ is the energy difference in sites $i$ and $j$, respectively. Accordingly, the hole mobility $(\mu)$ is estimated by Einstein equation: ${ }^{8}$

$$
\begin{gathered}
\mu=\frac{e D}{k_{\mathrm{B}} \mathrm{~T}} \\
D=\frac{1}{2 d} \sum_{n} r_{n}^{2} k_{n} p_{n}
\end{gathered}
$$

where $e$ and $D$ in numerator represent for the unit charge and diffusion coefficient. Correspondingly, to calculate $D$, a spatial dimensionality $d$ should be defined (here taken as 1 for amorphous morphology), and associated centroid to centroid distance $\left(r_{n}\right), k_{n}$, as well as the hopping probability for the $n$th hopping pathway ( $\left.p_{n}=k_{n} / \sum_{n} k_{n}\right)$ should be as the input to obtain the diffusion coefficient.
