Methods.

Preparation of the F-FeNC and FeNC catalysts. 65 mg of $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ and 2.2 g of $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ were dissolved in 250 mL methanol with 5 min sonication (solution I). 2.5 g of 2-methylimidazole and 260 mg of PFTA surfactants were dissolved in 250 methanol (Solution II). Solution I was added into solution II rapidly in a flask. After 24 h reaction with vigorous stirring at 60 °C, as-prepared product was collected by a centrifugation process and washed with methanol three times, and dried in a vacuum at 80 °C. The precursors were heated with a heating ramp of 35 °C min^{-1} to 1000 °C for 1 h under an Ar environment, and then cooled to room temperature. The samples prepared by 169:1, 85:1 and 68:1 were denoted as F-FeNC-1, F-FeNC-2, and F-FeNC-3, respectively. For comparison, the FeNC sample was also prepared with the same method but without using PFTA surfactant. The F-NC reference was prepared by adding the same PFTA with F-FeNC-2 but without Fe source.

Physical characterization. Powder X-ray diffraction (PXRD) was carried out to characterize the crystalline phases of precursors and catalysts on a Rigaku SmartLab diffractometer with Cu K α X-rays ($\lambda = 1.5406 \text{ \AA}$) and a scanning speed of 0.4° min^{-1} . The elemental quantifications of catalysts were determined by X-ray photoelectron spectroscopy (XPS), which were conducted on Axis Ultra DLD imaging XPS using hybrid mode (700 x 300 μm) with 80 pass energy for survey spectra, as well as 20 pass energy for high-resolution spectra of elements. Inductively coupled plasma atomic emission spectroscopy (ICP-AES) was employed to measure the Fe loading (VISTA MPX, Varian Inc.). The preparation of the sample for ICP measurement was as

followed: Sample (2 mg) in a quartz boat was heated in atmosphere at 800 °C for 1 h to remove carbon support. The concentrated nitric acid (3 mL) was used to dissolve iron oxide in the quartz boat to obtain iron extract. The above extract then was transferred to a 50 mL volumetric flask and made up to volume with ultrapure water. The porous structure was analysed using N₂ adsorption-desorption experiments carried out at 77 K on a Quantachrome SI-MP Instrument. Non-local density functional theory (NLDFT) model was used to determine the pore size distributions. Before measurements, samples were degassed at 120 °C for 24 h under vacuum. Transmission electron microscopy (TEM) and high-resolution TEM (HR-TEM), together with element mapping images were acquired on Tecnai G2 F30 S-Twin (FEI, Netherlands) working at 200 kV. High-angle annular dark-field scanning TEM (HAADF-STEM) and aberration-corrected (AC-HAADF-STEM) images were collected using Theims Z field emission electron microscope (FEI, Netherlands) working at 200 kV. The Raman spectra of pellet samples were measured with a Bruker RFS 100/S Raman spectrometer excited by a 532 nm laser. The Raman spectra of three random spots were collected for each sample. X-ray absorption spectroscopy (XAS) experiments were carried out at the 1W1B station of the Beijing Synchrotron Radiation Facility (BSRF) that was operated at 2.5 GeV with a maximum current of 250 mA. Data reduction, analysis and EXAFS fitting were performed using the ATHENA module implemented in the IFEFFIT software packages according to the standard procedures.

⁵⁷Fe Mössbauer Spectroscopy. Mössbauer spectra were obtained by using a ⁵⁷Co/Rh source in transmission mode at room temperature. Both samples (80–100 mg) are

prepared in a sample holder (diameter: 15 mm) covered by tesa tape, and the measurements were carried out in a velocity range of $\pm 6.8 \text{ mm s}^{-1}$ at room temperature. Calibration of the velocity axis was done with respect to α -Fe. While the initially obtained spectrum covered the range of 1024 channels, due to the low iron content in the samples and low signal to noise ratio, all original spectra and the calibration file were converted to 512 channels, to improve the count statistics. Thus after folding and calibration, 256 data points cover the overall velocity range. The “Recoil” program was used to fit the data.

Electrochemical measurements. Electrochemical measurements were performed using a standard three-electrode system controlled by a CHI 760E electrochemical station (CH Instruments, Inc., Shanghai). A graphite rod and an Ag/AgCl (4 M KCl) electrode were used as a counter electrode and reference electrode, respectively. A rotating disk electrode (RDE) with a glassy carbon disk (5.0 mm diameter) and a rotating ring-disk electrode (RRDE) electrode with a Pt ring (6.25 mm inner diameter and 7.92 mm outer diameter) and a glassy carbon disk (5.61 mm diameter) served as the substrate for the working electrodes. Before use, RDE/RRDE electrodes were polished using aqueous alumina suspensions (3.0 to 0.05 μm). The catalytic ink was prepared by blending 2.5 mg catalyst with 500 μL of a mixture solution containing 490 μL of ethanol and 10 μL Nafion solution (5 wt%) followed by ultrasonication. A certain volume of ink was pipetted on the disk electrode to yield a uniform film with a catalytic loading of 0.6 mg cm^{-2} . Cyclic voltammetry (CV) measurements were carried out in O_2 -saturated electrolyte solution at 50 mV s^{-1} to activate the catalysts until the CV

profile was stable. ORR polarization curves were recorded with a sweep speed of 5 mV s⁻¹ at a rotating rate of 900 rounds per minute (rpm). Four-electron selectivity by RRDE technique was determined by measuring the ring current at 1.3 V and calculating the H₂O₂ yield. Catalyst durability was tested by potential cycling from 0.6 to 1.0 V in O₂-purged 0.5 M H₂SO₄ at a scan rate of 50 mV s⁻¹. A commercial Pt/C catalyst (20 wt% Pt on carbon; Fuel Cell Store) was served as a reference catalyst with a Pt loading of 0.1 mg cm⁻² in O₂-saturated 0.1 M HClO₄ solution.

The yield of hydrogen peroxide and the number of electron transfers were calculated by the following equations:

$$H_2O_2(\%) = 200 \times \frac{\frac{i_r}{N}}{i_d + \frac{i_r}{N}}$$
$$n = 4 \times \frac{\frac{i_d}{i_r}}{i_d + \frac{i_r}{N}}$$

Where i_r is the ring current, i_d is the disk current, and N = 0.37 is the Pt ring current collection efficiency.

Preperation of the Membrane Electrode Assemblies (MEA). A catalyst ink suspension was prepared by dispersing 80 mg Pt/C Elyst Pt20 0390 (Umicore AG&Co. KG.) in 800 μl H₂O, 800 μl NafionTM (PFSA 5 wt%) and 1600 μl isopropanol for the anode side. The cathode ink suspension was prepared by dispersing 80 mg of F-FeNC-2 catalyst in 276 μl H₂O, 987 μl NafionTM (PFSA 5 wt%) and 1974 μl isopropanol. All catalyst inks were dispersed in an ultrasonic bath for 1 h, followed by spray coating on a gas diffusion layer (GDL, Freudenberg SE H23C9) with an area of 4.84 cm². The obtained loadings were 0.21 mg_{Pt} cm⁻² for the anode gas diffusion

electrode (GDE) and 2 mg_{catalyst} cm⁻² for the cathode GDE. By hot pressing the anode and cathode GDE with a Nafion N212 membrane (Quintech GmbH) at 125°C and 4 bar for 2 minutes the MEA was fabricated.

For the preparation of the Pt/C reference catalyst on the cathode side, 10 mg Pt/C Elyst Pt50 0550 (Umicore AG& Co. KG.) and 90 mg Ketjenblack 300 were dispersed in 345µl water, 1234 µl Nafion™ (PFSA 5 wt%) and 2468 µl isopropanol. The catalyst ink suspension was dispersed in an ultrasonic bath for 1.5 h followed by spray coating and hot pressing analog to the other catalysts with the exception of a catalyst loading of 0.1 mg_{Pt} cm⁻² and a pressure of 18 bar, respectively.

Fuel Cell Testing: Fuel Cell measurements were carried out in a 850e fuel cell test station (Scribner Associates Inc., North Carolina) at 81 °C with 96 % humidification and 1 bar gauge back pressure. The gas flows for H₂ and Air were set at 200 sccm. The measurement protocol consisted of started with recording the open-circuit voltage for 180 s, followed by a polarization curve measured stepwise starting at a current of 0 A and increasing the current with a stepwidth of 0.03 A every 10 s until the cutoff condition of 0.2 V was reached. The stability was measured by applying a constant potential of 500 mV for 24 h. In the case of the Pt/C reference a breakin procedure was carried out by cycling 80 times between 600 mV and 300 mV with a holding time of 1 min for each potential before starting the measurement protocol.

Computational details.

Models: The two-dimensional models of graphene hexagonal supercell, consisting of 73 atoms, is separated by a vacuum region of 15 Å along the direction normal to the

sheet plane to avoid artificial interactions between graphene layers. A series of models of five-coordinated $\text{FeN}_{(2+2)}$ site dispersed on F N co-doped graphene and corresponding intermediates (*OOH, *OH, and *O) was built in Fig-S1.

Calculated details. All the density functional theory (DFT) calculations were constructed and implemented in the Vienna ab initio simulation package (VASP).^{1, 2} Using the electron exchange and correlation energy was treated within the generalized gradient approximation in the Perdew–Burke–Ernzerhof functional (GGA-PBE),³ the calculation were done with a plane-wave basis set defined by a kinetic energy cutoff of 450 eV. The geometry optimization and energy calculation were finished when the electronic self-consistent iteration and force were reach 10^{-5} eV and 0.02 eV \AA^{-1} , respectively.

The Adsorption Energy. The adsorption energy (ΔE_{ads}) of the key ORR intermediates, including *OOH, *O, and *OH, was calculated relative to H_2O and H_2 under conditions of $T = 298.15$ K, $\text{pH} = 0$, and $U = 0$ V (vs. SHE) according to following equations:

$$\Delta E_{*\text{OOH}} = E_{*\text{OOH}} + 3/2 E_{\text{H}_2} - E_* - 2 E_{\text{H}_2\text{O}}$$

$$\Delta E_{*\text{O}} = E_{*\text{O}} + E_{\text{H}_2} - E_* - E_{\text{H}_2\text{O}}$$

$$\Delta E_{*\text{OH}} = E_{*\text{OH}} + 1/2 E_{\text{H}_2} - E_* - E_{\text{H}_2\text{O}}$$

Where * represents the adsorption sites associated with FeN_4 doped graphene. The above ΔG_{ads} is defined as the reaction free energies of the following reactions.

The Gibbs free energy variation. The change in Gibbs free energy (ΔG) of each adsorbed intermediate is calculated based on the computational hydrogen electrode method developed by Nørskov et al.³ At standard condition ($T = 298.15$ K, $pH = 0$, and $U = 0$ V (vs. standard hydrogen electrode, SHE), the free energy G is defined as the following equation:

$$\Delta G = \Delta E + \Delta E_{ZPE} - T\Delta S + \Delta G_{pH} + \Delta G_U$$

Where ΔE is the energy change obtained from DFT calculation, ΔE_{ZPE} is the difference between the adsorbed state and gas, which was calculated by summing vibrational frequency for all model based on the equation: $E_{ZPE} = 1/2\sum hV_i$ (T is the temperature (298.15 K) in the above reaction system, and ΔS represents the difference on the entropies between the adsorbed state and gas phase. The entropies of free molecules were obtained from NIST database (<https://janaf.nist.gov/>). $\Delta G_{pH} = -kT\ln[H^+] = pH \cdot kT \cdot \ln 10 = -0.0591pH$ is used to correct the free energy of $H^+ + e^-$ referenced by a SHE at various pH values. $\Delta G_U = -neU$, where U is the applied electrode potential and n is the number of electrons transferred. Therefore, the equilibrium potential U^0 for ORR at $pH = 13$ was determined to be 0.462 V (vs. SHE).

The free energy of $O_2(g)$ was derived as $G_{O_2(g)} = 2G_{H_2O(l)} - 2G_{H_2} + 4.92$ eV, and the free energy of OH^- was calculated by $G_{OH^-} = G_{H_2O(l)} - G_{H^+}$, which the energy of H^+ is approximately equal to the energy of $1/2H_2$. The overall reaction of O_2 reduction to OH^- in a alkaline environment is: $O_2 + H_2O(l) + H^+ + e^- + * \rightarrow OOH^* + OH^-$, which is divide into the four fundamental reactions as following:

OOH^* , O^* and OH^* present the OOH, O and OH moieties on the adsorption site.

Theoretical ORR Overpotential. The theoretical ORR overpotential (η_{SHE} , vs. SHE)

associated with different active sites was calculated according to following equation

$\eta_{\text{SHE}} = 0.462 \text{ V} + \Delta G_{\text{max}}$, where 0.462 V is defined as the equilibrium potential of the overall 4-electron ORR at the standard state, and ΔG_{max} represents the most positive free energy variation associated with the proton-electron-transfer steps.

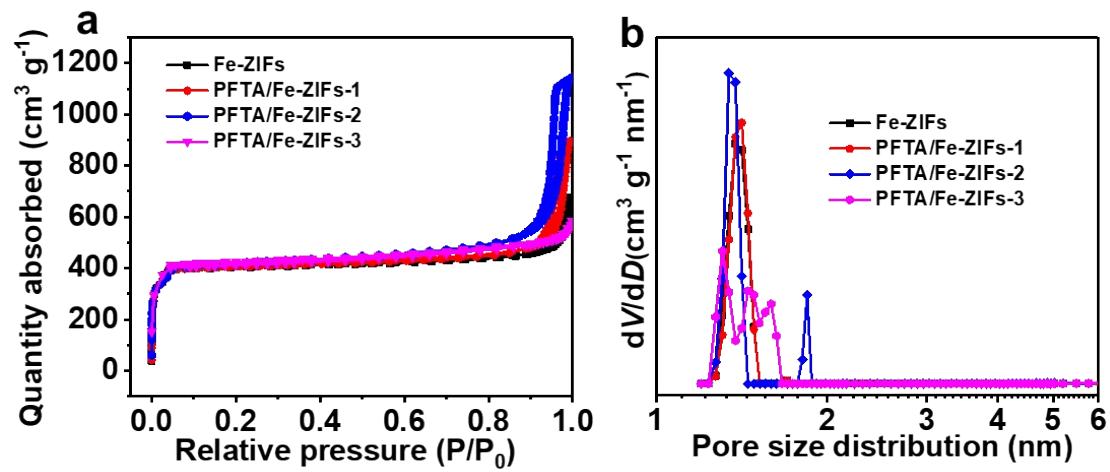

Fig. S4. (a) N_2 adsorption/desorption isotherms of Fe-ZIFs, PFTA/Fe-ZIFs-1, PFTA/Fe-ZIFs-2, and PFTA/Fe-ZIFs-3 and the corresponding pore size distributions processed from NLDFT approach (b). All the PFTA/Fe-ZIFs showed a slightly larger Brunauer-Emmett-Teller (BET) surface areas of $\sim 1680 \text{ m}^2 \text{g}^{-1}$ than that of Fe-ZIFs ($1444 \text{ m}^2 \text{g}^{-1}$). The larger BET surface area is caused by the involved PFTA surfactants into micropores of ZIFs and the new micropores. The emergence of new larger micropores is very likely caused by the formation of defects in ZIF-8 due to the coordination of PFTA and metals.
