${ }^{2}$ Measured vs. SCE electrode; scan rate: $50 \mathrm{mV} \mathrm{s}^{-1}$, supporting electrolyte $2 \% \mathrm{DMF} / 5 \mathrm{mM}$ Tris$\mathrm{HCl} / 50 \mathrm{mM} \mathrm{NaCl}$; complex concentration: $2.5 \times 10^{-4} \mathrm{M}$.
${ }^{\mathrm{b}}$ Differential pulse voltammetry (DPV), scan rate: $2 \mathrm{mV} \mathrm{s}^{-1}$, pulse height 50 mV .

## Calculations of BSA binding parameters

Fluorescence quenching property can be described by the Stern-Volmer equation [1]:

$$
\mathrm{F}_{0} / \mathrm{F}=1+\mathrm{K}_{\mathrm{SV}}[\mathrm{Q}]=1+\mathrm{k}_{\mathrm{q}} \tau_{0}[\mathrm{Q}]
$$

where $\mathrm{F}_{0}$ and F are the steady-state fluorescence intensities in the absence and the presence of quencher, respectively. $\mathrm{K}_{\mathrm{SV}}$ is the Stern-Volmer quenching constant and $[\mathrm{Q}]$ is the concentration of quencher. The plot of $\mathrm{F}_{0} / \mathrm{F}$ versus $[\mathrm{Q}]$ shows the value of $\mathrm{K}_{\mathrm{sv}}$. According to the above equation

$$
\mathrm{K}_{\mathrm{SV}}=\mathrm{k}_{\mathrm{q}} / \tau_{0}
$$

where $\mathrm{K}_{\mathrm{q}}$ is the quenching rate constant and $\tau_{0}$ is the fluorescence lifetime of protein in the absence of quencher, the value of $\tau_{0}$ is considered to be $10^{-8} \mathrm{~s}[2]$.

The binding constant $\left(\mathrm{K}_{\mathrm{b}}\right)$ and the numbers of binding sites ( n ) can be determined using the following equation [3]:

$$
\log \left[\mathrm{F}_{0}-\mathrm{F} / \mathrm{F}\right]=\log \mathrm{K}_{\mathrm{b}}+\mathrm{n} \log [\mathrm{Q}]
$$

where $\mathrm{K}_{\mathrm{b}}$ is the binding constant, reflecting the degree of interaction of the BSA and complex, and n is the number of binding sites. The plots of $\log \left[\left(\mathrm{F}_{0}-\mathrm{F}\right) / \mathrm{F}\right]$ versus $\log [\mathrm{Q}]$ gives a straight line. The values of n and $\mathrm{K}_{\mathrm{b}}$ can be calculated from the slope and intercept of the linear plot respectively.
The thermodynamic parameters can be calculated from the following Van't Hoff equations [4, 5] to elucidate the binding forces between complex and BSA.

$$
\begin{gathered}
\ln \left(\mathrm{K}_{2} / \mathrm{K}_{1}\right)=\left(1 / \mathrm{T}_{1}-1 / \mathrm{T}_{2}\right) \Delta \mathrm{H}^{\circ} / \mathrm{R} \\
\Delta \mathrm{G}^{\circ}=\Delta \mathrm{H}^{\circ}-\mathrm{T} \Delta \mathrm{~S}^{\circ}=-\mathrm{R} \ln \mathrm{~K}
\end{gathered}
$$

where $K_{1}$ and $K_{2}$ are equilibrium binding constants at temperature $T_{1}$ and $T_{2}$, respectively, and $R$ is the gas constant.
