### Single crystal X-ray diffraction studies

A BRUKER Quest X-ray (fixed-Chi geometry) diffractometer with a PHOTON II detector was employed for crystal screening, unit cell determination, and data collection. The goniometer was controlled using the APEX3 software suite.<sup>1</sup> The sample was optically

centered with the aid of a video camera such that no translations were observed as the crystal was rotated through all positions. The X-ray radiation employed was generated from a Mo- $\mu$ s X-ray tube ( $K_{\alpha} = 0.71073\text{\AA}$ ). Integrated intensity information for each reflection was obtained by reduction of the data frames with the program APEX3.<sup>1</sup> The integration method employed a three dimensional profiling algorithm and all data were corrected for Lorentz and polarization factors, as well as for crystal decay effects. Finally the data was merged and scaled to produce a suitable data set. The absorption correction program SADABS was employed to correct the data for absorption effects.<sup>2</sup> A solution was obtained readily ( $Z=4$ ;  $Z'=0.5$ ) using XT/XS in APEX3.<sup>1,3</sup> Hydrogen atoms were placed in idealized positions and were set riding on the respective parent atoms. All non-hydrogen atoms were refined with anisotropic thermal parameters. Appropriate restraints and constraints were added to keep the bond distances, angles, and thermal ellipsoids meaningful. Absence of additional symmetry and voids were confirmed using PLATON (ADDSYM). The structure was refined (weighted least squares refinement on  $F^2$ ) to convergence.<sup>3,4</sup>

**DFT Calculations**

The experimentally elucidated structures of compound 1 and 2 were geometry optimized at the Density Functional Theory (DFT) level using the CP2K package.<sup>5</sup> In these simulations, the positions of atoms of the framework were relaxed while the unit cell parameters were kept fixed at the values determined experimentally. All the structural optimizations were done using Perdew-Burke-Ernzerhof (PBE) functional along with a combined Gaussian basis set and pseudo potential.<sup>6</sup> For Carbon, Oxygen, and Hydrogen, a triple zeta (TZVP-MOLOPT) basis set was considered, while a double zeta (DZVP-MOLOPT) was applied for silicon and tin.<sup>7</sup> The pseudo potentials used for all of the atoms

were those derived by Goedecker, Teter and Hutter.<sup>8</sup> The van der Waals interactions were taken into account via the use of semi-empirical dispersion corrections as implemented in the DFT-D3 method.<sup>9</sup> The final optimized structures were used to simulate their powder diffraction patterns in Materials Studio. The Simulated patterns were obtained using the Reflex powder diffraction module of the material studio.
