Details of computational methods

ORR and OER processes are reversible. Previous research showed that ORR and OER process on SAC systems mainly followed the four-electron mechanism under alkaline conditions according to the electrochemical framework developed by Nørskov.¹ The overall reaction could be expressed as $O_2 + 2H_2O + 4e^- \leftrightarrow 4OH^-$. The whole reaction process was described as the following five elementary reactions (1)-(5):

The first step (S1) is a pure chemical adsorption/desorption reaction involving no electron transfer. * represents clean catalyst surface, O_2^* , OOH^* , O^* and OH^* represent intermediates adsorbed on different catalyst surfaces (FeN₄C, FeN₃SC, Pt(111), RuO₂(110)), respectively. The corresponding reaction energies are expressed as:

$$\Delta E_{O_2^*} = E_{O_2^*} - E^* - (2E_{H_2O} - 2E_{H_2})$$

$$\Delta E_{OOH^*} = E_{OOH^*} - E^* - (2E_{H_2O} - \frac{3}{2}E_{H_2})$$

$$\Delta E_{O^*} = E_{O^*} - E^* - (E_{H_2O} - E_{H_2})$$

$$\Delta E_{OH^*} = E_{OH^*} - E^* - (E_{H_2O} - \frac{1}{2}E_{H_2})$$

where E_{H_2O} and E_{H_2} are the DFT electron energies of H_2O and H_2 molecules in the gas phase, respectively. E^* , $E_{O_2^*}$, E_{OOH^*} , E_{O^*} , E_{OH^*} are the energies of clean catalyst surface and adsorbed system O_2^* , OOH^* , O^* , OH^* respectively. The Gibbs free energy change of ORR/OER was calculated according to $\Delta G = \Delta E + \Delta ZPE - T\Delta S + \Delta pH$, where ΔZPE and ΔS represent the zero point energy and entropy change from the initial state to the end state of the reaction process, respectively, T is 298.15 K. VASPKIT, a postprocessing tool in the VASP code, was adopted to deal with electronic structures.² The free energy of liquid $H_2O(l)$ molecules was calculated at the gas phase of T=298.15 K with a pressure of P=0.035 bar. The free energy of O_2 was calculated according to

the reaction $O_2 + 2H_2 = 2H_2O$ (the free energy change is 4.92 eV). Δ_{pH} is the free energy correction at any pH value, $\Delta G_{pH} = -kT \ln[H^+] = -kT \ln 10 \times pH$. The theoretical overpotential (η) under standard conditions is calculated according to the following equation under alkaline conditions:

$$\eta^{ORR} = \{\Delta G1, -[\Delta G2, \Delta G3, \Delta G4, \Delta G5]^{max}/e + 0.460\text{ V}\}^{max}, \quad \eta^{OER} = \{\Delta G1, [\Delta G2, \Delta G3, \Delta G4, \Delta G5]^{max}/e - 0.460\text{ V}\}^{max}.$$

Mechanism of ORR on Pt(111)

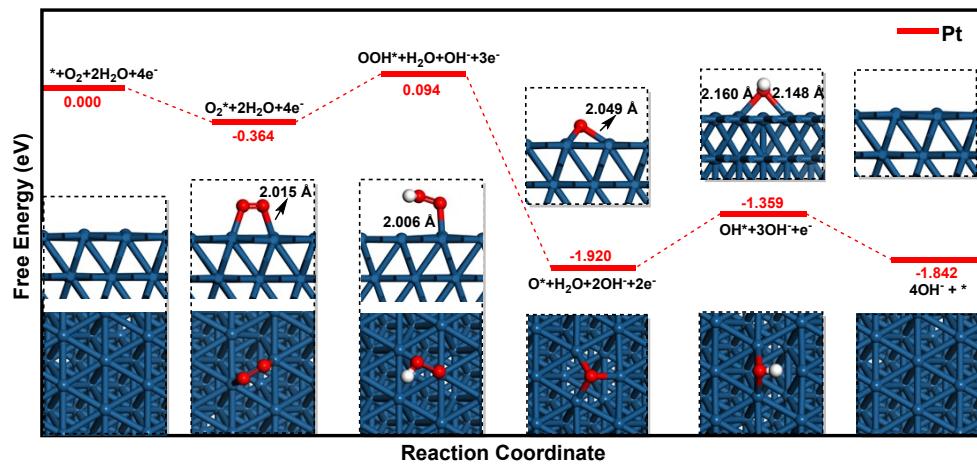

Figure S1 Energy profile of ORR catalyzed by Pt and optimized structures for related species (pH=13).

Mechanism of OER on FeN₄C, FeN₃SC and RuO₂

For FeN₄C, the reactant OH⁻ arrives near Fe-N₄ site. Due to the adsorption of OH⁻ by the positively charged Fe atom, Fe-O bond is formed. The first electron is released to obtain **OH@FeN₄C** intermediate. The energy decreases from -1.842 V to -2.051 eV, indicating that OH⁻ tends to adsorb on FeN₄C surface. Then, **OH@FeN₄C** releases the second electron and is oxidized to **O@FeN₄C** with further reduced energy of -0.020 eV. In the third electron-release step, the O-OH bond is formed to give **OOH@FeN₄C** intermediate. The instability of OOH on FeN₄C surface increases the free energy by 1.605 eV. It makes the step **O@FeN₄C**→**OOH@FeN₄C** difficult to proceed with. This step is the RDS of FeN₄C surface. Subsequently, **OOH@FeN₄C** undergoes the final electron-release step to give intermediate **O₂@FeN₄C** with declined energy of -0.414 eV. The final product O₂ is obtained by desorbing from FeN₄C surface with elevated energy of 0.880 eV. In summary, OH⁻ is oxidized to the final product O₂ through four electron-release steps and one desorption step on FeN₄C surface. The first (OH⁻→**OH@FeN₄C**), the second (**OH@FeN₄C**→**O@FeN₄C**) and the fourth (**OOH@FeN₄C**→**O₂@FeN₄C**) steps are exergonic, whereas the third (**O@FeN₄C**→**OOH@FeN₄C**) and last desorption (**O₂@FeN₄C**→O₂) steps are endergonic. The third step **O@FeN₄C**→**OOH@FeN₄C** has the highest energy demand of 1.605 eV.

For FeN₃SC surface, the OER process is similar to that of FeN₄C. OH⁻ first reaches near the active site Fe-N₃|S. **OH@FeN₃SC** is obtained after releasing the first electron with the reduced free energy of -0.329 eV. In the second electron-transfer process, **OH@FeN₃SC** reacts with OH⁻ to generate the intermediate **O@FeN₃SC** and a H₂O molecule. The shedding of H proton causes the bond length of Fe-O to be shortened to 1.669 Å in **O@FeN₃SC** (1.876 Å in **OH@FeN₃SC**) with the enhanced Fe-O interaction. The free energy increased by 0.199 eV after the step. Then the obtained **O@FeN₃SC** reacts with OH⁻ and releases the third electron to form **OOH@FeN₃SC**. The bonding of O-OH causes the Fe-O bond length to be stretched to 1.848 Å with increased free energy of 1.276 eV. The step is the RDS of OER on FeN₃SC surface, the same as FeN₄C. The much lower barrier makes facile RDS compared with FeN₄C. Subsequently, **OOH@FeN₃SC** releases the fourth electron to form **O₂@FeN₃SC** and the second H₂O molecule. The break of the OO-H bond induces the shortened O-O bond length of 1.355 Å in **O₂@FeN₃SC** (1.478 Å in **OOH@FeN₃SC**) with the

declined free energy of -0.325 eV. Finally, the adsorbed O₂ is dissociated from the FeN₃SC surface via a pure chemical desorption step. The free energy increased by 1.021 eV. In summary, OH⁻ undergoes four electron-release steps and one chemical desorption step on FeN₃SC surface to be oxidized to the final product O₂. The first (OH⁻→OH@FeN₃SC) and the fourth (OOH@FeN₃SC→O₂@FeN₃SC) steps are exergonic, whereas the second (OH@FeN₃SC→O@FeN₃SC), the third (O@FeN₃SC→OOH@FeN₃SC) and the last desorption (O₂@FeN₃SC→O₂) steps are endergonic. The third step O@FeN₃SC→OOH@FeN₃SC has the highest energy demand of 1.276 eV.

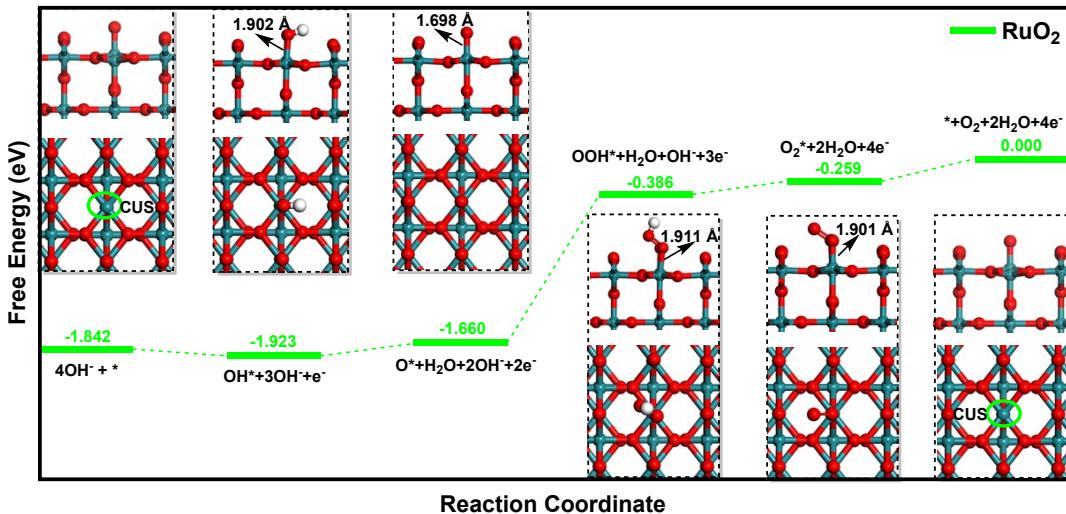

Figure S2 Energy profile of OER catalyzed by RuO₂ and optimized structures for related species (pH=13).

The OER mechanism on RuO₂(110) surface is investigated at U=0 V, pH=13, as shown in Figure S2. The coordination unsaturated site (CUS) Top Ru was considered as the active site on the RuO₂(110) surface.¹⁻² First, OH⁻ is adsorbed on Top Ru and gives the first electron to obtain OH@RuO₂ with Ru-O bond length of 1.902 Å. The adsorption energy of OH@RuO₂ is -3.347 eV. The Gibbs free energy decreases from -1.842 eV to -1.923 eV. Then, OH@RuO₂ releases the second electron to obtain O@RuO₂ (The adsorption energy is -3.845 eV) with increased energy of 0.263 eV. The Ru-O bond length is shortened to 1.698 Å. Then, O@RuO₂ releases the third electron and is oxidized to OOH@RuO₂ (The adsorption energy is -1.566 eV), with increased free energy

of 1.275 eV. The bonding of O-OH re-stretches the Ru-O bond to 1.911 Å. This step is the RDS on RuO₂(110) surface, the same as FeN₄C and FeN₃SC surfaces. The energy trend of the first three electron-release steps is consistent with that of FeN₃SC surface. Subsequently, the fourth electron-transfer step gives **O₂@RuO₂**, the OO-H bond breaks and the Ru-O bond length is 1.901 Å with slight change (1.911 Å in **OOH@RuO₂**) due to the similar adsorption energy of -1.515 eV as **OOH@RuO₂** (-1.566 eV). The free energy increases by 0.126 eV. Compared with FeN₄C and FeN₃SC (-2.123 eV and -2.279 eV), the desorption of O₂ on RuO₂(110) surface becomes easier due to the instability of **O₂@RuO₂** (-1.515 eV). The free energy increases by 0.259 eV after O₂ desorption.

In summary, OH⁻ undergoes four electron-transfer steps and one O₂-desorption step to evolve oxygen on RuO₂(110) surface. For the five steps, only the first step (OH⁻→**OH@RuO₂**) is exergonic, while the following four steps (**OH@RuO₂**→**O@RuO₂**, **O@RuO₂**→**OOH@RuO₂**, **OOH@RuO₂**→**O₂@RuO₂**, **O₂@RuO₂**→O₂) are endergonic. The third step (**O@RuO₂**→**OOH@RuO₂**) has the highest energy demand of 1.275 eV.

Spin density and band structures of FeN₄C and FeN₃SC

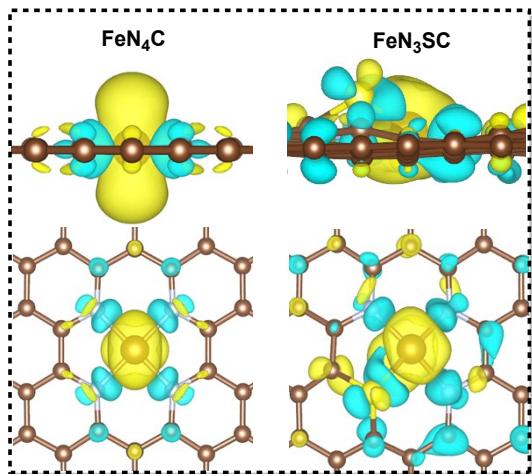

Figure S3 Spin density distributions of FeN₄C and FeN₃SC slabs. Yellow and turquoise iso-surfaces correspond to spin-up and spin-down density, respectively. The iso-surface levels are 0.002 eÅ⁻³.

For both Fe-N₄ and Fe-N₃|S, the spin mainly locates on Fe and the coordination N atoms. The high spin of the active site stabilizes an unpaired electron in antibonding π^* orbitals of the O atom far away from the H atom in the OOH intermediate through exchange interactions.^{1, 2}

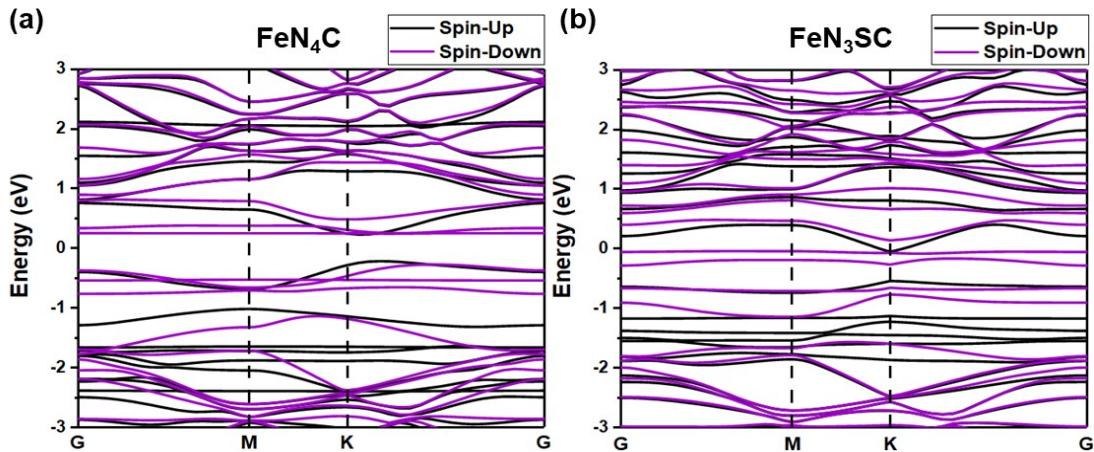

Figure S4 Band structures of (a) FeN_4C and (b) FeN_3SC slabs. The Fermi level is set at 0 eV.

For FeN_4C in Figure S4a, the valence band (VBM) of the spin-up channel is located at -0.215 eV and the conduction band (CBM) is located at 0.231 eV, so the band gap of the spin-up channel is 0.446 eV. The valence band and conduction band of the spin-down channel are located at -0.271 eV and 0.245 eV, respectively, so the band gap of the spin-down channel is 0.516 eV. Accordingly, the total band gap of FeN_4C is 0.447 eV. For FeN_3SC in Figure S4b, the VBM and the CBM of the spin-up channel are located at 0.000 eV and 0.028 eV, with a band gap of 0.028 eV. The VBM and CBM of the spin-down channel are located at -0.041 eV and 0.140 eV, with a band gap of 0.181 eV. That is, the total band gap of FeN_3SC is 0.028 eV. S-doping reduces the FeN_4C band gap and enhances the electrical conductivity, which is conducive to the electron transport in the catalytic reaction process.

DOS and d-band center of OOH@FeN₄C and OOH@FeN₃SC

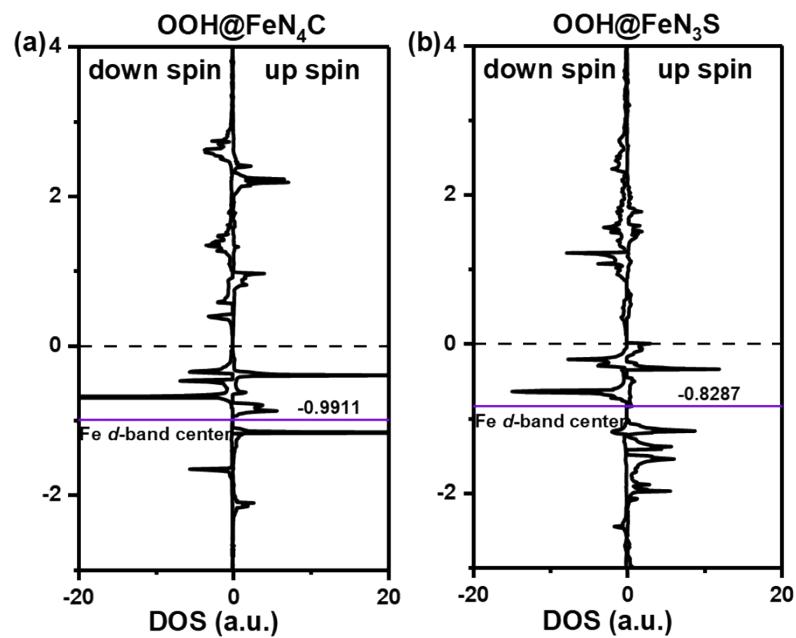

Figure S5 Density of states of (a) OOH@FeN₄C and (b) OOH@FeN₃SC slabs. The Fermi level is set at 0 eV.

ORR and OER on $\text{FeN}_2\text{S}_2\text{C}$, FeNS_3C and FeS_4C

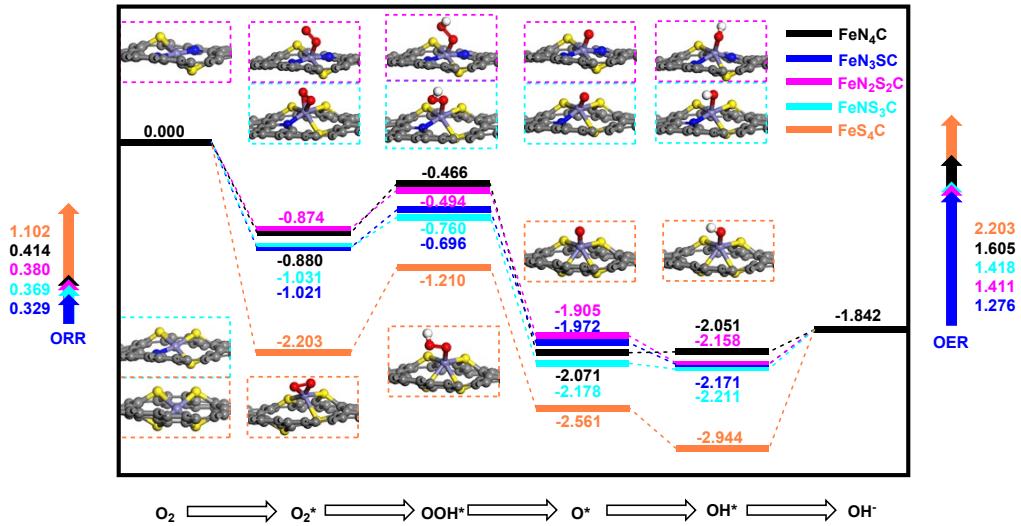

Figure S6 Energy profile of ORR catalyzed by FeN_4C , FeN_3SC , $\text{FeN}_2\text{S}_2\text{C}$, FeNS_3C and FeS_4C . The side views of related species for $\text{FeN}_2\text{S}_2\text{C}$, FeNS_3C and FeS_4C are displayed in pink, turquoise and orange boxes, respectively (pH=13).

O_2 adsorption at the doped S atom

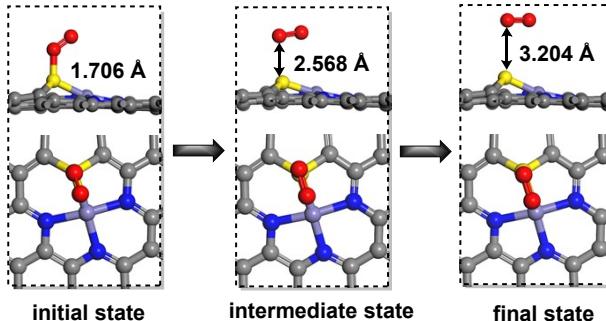

Figure S7 The structure optimization of O_2 adsorption at the protruding S

We investigated the O_2 species adsorption at the protruding S atom of the catalyst. Figure S7 shows the optimization process of the $\text{O}_2@\text{FeN}_3\text{SC}$ structure, in which O_2 gradually moves away from S atoms. In the final configuration, the distance between O_2 and S atoms is 3.204 \AA , and the corresponding energy is 1.419 eV higher than that adsorbed on Fe center. Therefore, O_2 cannot be stably adsorbed on S, which is not conducive to the subsequent reaction steps.
