X-ray diffraction data

Single crystals of **5e** and **5o** were grown from DMF. Data collection for samples **5e** and **5o** were performed on a Bruker SMART APEX II diffractometer equipped with a Photon-II area-detector and a graphite monochromator for MoK α radiation ($\lambda = 0.71073 \text{ \AA}$, phi and omega scans). Frames were integrated using the Bruker SAINT software package^[1] by a narrow-frame algorithm. A semiempirical absorption correction was applied with the SADABS^[2] program using the intensity data of equivalent reflections. The structures were solved with a dual-space method with SHELXT program^[3] and refined by the full-matrix least-squares technique against F^2_{hkl} in anisotropic approximation for non-hydrogen atoms with SHELXL^[4] program. Hydrogen atoms connected to nitrogen atoms were found from difference Fourier synthesis and refined isotropically. Other H atoms were placed in calculated positions and refined in the riding model with $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C}_m)$ for methyl groups and $1.2U_{\text{eq}}(\text{C}_i)$ for other carbon atoms to which corresponding H atoms are bonded.
