Definition of zipper nomenclature. The following nomenclature is used to describe the relative arrangement between two monomers on opposing strands in a duplex. The number n describes the distance measured in number of base-pairs and has a positive value if a monomer is shifted toward the 5'-side of its strand relative to a second reference monomer on the other strand. Conversely, n has a negative value if a monomer is shifted toward the 3'-side of its strand relative to a second reference monomer on the other strand.

Figure S22. Representative thermal denaturation profiles of double-stranded probes, duplexes between individual probe strands and 33-mer ssDNA harboring complementary target regions, and unmodified reference duplex **DNA1:DNA2**. For experimental conditions, see Table 1.

Figure S23. Representative thermal denaturation profiles of double-stranded probes, duplexes between individual probe strands and 33-mer ssDNA harboring complementary target regions, and unmodified reference duplex **DNA1:DNA2**. For experimental conditions, see Table 1.

Figure S24. Representative thermal denaturation profiles of probes used in FISH experiments (**DYZ-NIP = ON23/24:ON25/26**), duplexes between individual probe strands and 33-mer ssDNA harboring complementary target regions, and reference duplex **DNA3:DNA4** recorded in medium (left) or high (right) salt buffer. For experimental conditions, see Table 1.

Figure S25. Representative thermal denaturation profiles of probes used in FISH experiments (**DYZ-REF**), duplexes between individual probe strands and 33-mer ssDNA harboring complementary target regions, and reference duplex **DNA3:DNA4** recorded in medium buffer. For experimental conditions, see Table 1.

Supplemental discussion regarding denaturation profiles and T_m values. While evaluating the stability of the different duplex segments of **NIP1**, we observed a transition for **ON1:ON3** at a temperature of ~45 °C. Based on our prior experience with these type of probes, this transition seemed unlikely to stem from melting of a 6-bp duplex with two energetic hotspots (the single-stranded overhangs were expected only to have a minor influence on the T_m value).^{S1} Indeed, when recording the thermal denaturation profile for **ON1** in absence of **ON3**, a transition at a similar temperature was observed prompting us to suggest that the ~45 °C transition likely is due to denaturation of a secondary structure entailing only **ON1** (Fig. S26). No other transitions were observed for **ON1:ON3**, prompting us to list “no transition” for **ON1:ON3** in Table 1.

ON1:ON4 displays a transition at 49 °C which is close to the T_m value observed for **ON1**-only (Fig. S26a). To determine if this transition is due to duplex formation between **ON1** and **ON4** or denaturation of a secondary structure entailing **ON1**-only, we recorded denaturation profiles for **ON1:ON4** and **ON1**-only at 10-fold higher strand concentrations. In both instances, denaturation curves were shifted to a higher, identical T_m value (~57 °C, Fig. S26b and c). A differential thermal denaturation curve (i.e., **ON1:ON4** – **ON1**-only) also displayed a T_m value of ~57 °C, seemingly suggesting concomitant heteroduplex (**ON1:ON4**) and homoduplex (**ON1**-only) formation when **ON1** and **ON4** are mixed. Further evidence supporting duplex formation between **ON1** and **ON4** was obtained from electrophoretic mobility shift assays conducted at non-denaturing conditions, as slower moving bands were observed when **ON1** and **ON4** were mixed (Fig. S27).

The denaturation profiles of **DNA1:ON7** and **DNA1:ON11** display two transitions (Fig. S28a and b). Analysis of the 33-mer **DNA1** strand using the OligoAnalyzer tool from Integrated DNA Technologies, hinted at possible intramolecular hairpin formation with an estimated T_m of ~25 °C. Indeed, denaturation profiles of **DNA1**-only suggest the presence of a transition below 30

°C (see Fig. S28a and b). Thus, it is reasonable to attribute the first transition to the denaturation of this secondary structure, and the second transition to the denaturation of the probe-target duplexes.

In light of the above and to clarify the nature of the transition observed at ~25 °C for **DNA1:ON3**, we constructed a differential thermal denaturation curve (i.e., **DNA1:ON3 - DNA1**), which suggests that **DNA1:ON3** forms a labile duplex ($T_m \sim 25.5$ °C, Fig. S28c).

Figure S26. (a) Representative thermal denaturation profiles of **ON1-only**, **ON4-only**, and **ON1:ON4** in medium salt buffer. Experiments were performed using a 0.5 μM concentration of each strand. b) Thermal denaturation profiles of **ON1:ON4** or c) **ON1** performed using 0.5 μM or 5 μM concentration of each strand. (d) Thermal denaturation profiles of **ON1**, **ON1:ON4** and differential profile (**ON1:ON4 – ON1**) at 5 μM concentration of each strand. For experimental conditions, see Table 1.

Figure S27. Representative gel electrophoretograms from non-denaturing PAGE aiming to determine if **ON1** forms a duplex with **ON4** in HEPES buffer. Experimental conditions are as outlined in Fig. 3.

Figure S28. Additional experiments to further clarify duplex formation between **DNA1** and **ON7**, **ON11** or **ON3**. Representative thermal denaturation profiles of a) **DNA1**-only, **ON7**-only, **DNA1:ON7** (1:1 ratio) and **DNA1:ON7** (1:2 ratio), b) **DNA1**-only, **ON11**-only, **DNA1:ON11** (1:1 ratio) and **DNA1:ON11** (1:2 ratio), and c) **DNA1**-only, **ON3**-only, **DNA1:ON3** and differential profile (**DNA1:ON3** – **DNA1**-only). For experimental conditions, see Table 1.

^a The unmodified **DNA3:DNA4** duplex ($T_m = 82.0$ °C) is the model dsDNA target, where **DNA3** = 5'-ACTGTGTGTTATATGCTGTTCTCAGCCCTACTG and **DNA4** = 3'-TGACACACAATATACGACAAGAGTCGGGATGAC. Thermal denaturation curves were recorded as described in Table 1 with the exception that in a high salt phosphate buffer was used ($[Na^+] = 710$ mM, $[Cl^-] = 710$ mM, pH 7.0 (NaH_2PO_4/Na_2HPO_4), $[EDTA] = 0.2$ mM), with each ON present at 0.5 μ M concentration. nt = no sigmoidal transition observed.

Figure S34. Matched/mismatched recognition complexes that would ensue upon recognition of complementary target **DH2** or non-complementary target **DH2-MM** by **DYZ-NIP**. Highlighted residues indicate the position of mismatched base-pairs.

Figure S35. Images from nd-FISH experiments in which different concentrations of toehold Invader probe **DYZ-TIP** or nicked Invader probe **DYZ-NIP** (1-6 ng per 200 μ l of PCR buffer) were incubated with fixed isolated nuclei from male bovine kidney cells for 3 h at 37.5 $^{\circ}$ C in a Tris buffer (20 mM Tris-Cl, 100 mM KCl, pH 8.0) and counterstained with DAPI as outlined in Fig. 7. High background was observed when **DYZ-NIP** and **DYZ-TIP** were used at 3 or 6 ng per 200 μ l of PCR buffer, whereas 1 ng per 200 μ l of PCR buffer yielded single Cy3-signals.

Figure S36. Image from nd-FISH experiments in which nicked Invader probe **DYZ-NIP** was incubated with isolated fixed nuclei from a female bovine endothelial cell line (15 ng per 200 μ l of PCR buffer, 3 h, 37.5 $^{\circ}$ C). Experimental conditions and image analysis was carried out as described in Fig. 7.
