### **Pu(OH)<sub>3</sub>(am) Synthesis Procedure**

A Pu(IV) stock solution in 2 M HClO<sub>4</sub> was reduced electrochemically with a platinized Pt-wire working electrode to Pu(III)<sub>aq</sub> by applying a potential range of -0.20 to -0.40 V (vs. SHE) with the use of an Ag/AgCl/3 M NaCl reference electrode (Metrohm) and a standard Pt electrode acting as counter electrode. The reference and counter electrodes were separated from the plutonium stock by ceramic diaphragms and Teflon capillaries filled with 1.7 M HClO<sub>4</sub> solutions attached to quartz tubes. The three electrodes were connected to a potentiostat (Princeton Applied Research Model 362) to control constant voltage. To avoid overheating, the current never exceeded 10 mA. The procedure was monitored by means of visible-near infrared (Vis-NIR) absorption spectroscopy on a single-beam diode array photometer ( $\lambda = 400\text{--}1020$  nm, Carl Zeiss AG, MSC-501). The electrochemically-prepared Pu(III) stock solution was precipitated as Pu(OH)<sub>3</sub>(am) by its slow addition to a 0.1 M TRIS buffer solution ( $\text{pH}_m = 9.47$ ) with 5 mM Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> redox buffering agent present. Following precipitation, the solid phase was washed with and subsequently suspended in a pH 11 NaOH solution. The resulting solid phase was used as the solubility-controlling solid phase in the undersaturation solubility studies in the presence of EDTA and calcium and as the reference material in the X-ray absorption near edge structure (XANES) study.

Table S1. Selected equilibrium constants ( $\log K^\circ$  or  $\log \beta^\circ$ ) for PHREEQC thermodynamic calculations of Pu(III)-EDTA solubility and speciation.

Reaction	$\log K^\circ$ or $\log \beta^\circ$	Reference
$\text{H}_4(\text{EDTA})(\text{cr}) \Leftrightarrow \text{EDTA}^{4-} + 4\text{H}^+$	$-(27.220 \pm 0.200)$	1

Figure S1. Pourbaix diagram of the Pu-EDTA system at  $[\text{Pu}] = 1.1 \text{ mM}$ ,  $[\text{EDTA}] = 1 \text{ mM}$ ,  $I = 0.1 \text{ M}$ , and  $0 \text{ M CaCl}_2$  calculated from values in Tables S1 and S2. Experimental  $\text{pH}_m$  and  $pe$  measurements are shown for experiments conducted in the presence of  $\text{Sn(II)}$  (green diamonds) or in the presence of dithionite (DT; red triangles). Solid black lines correspond to redox borderlines between aqueous plutonium species and dashed black lines represent redox borderlines between solid plutonium species.

Figure S2. Pu L<sub>III</sub>-edge XANES spectra measured *in-situ* for the aqueous phase of Pu(OH)<sub>3</sub>(am) equilibrated with 1 mM EDTA and  $I = 0.1$  M at  $\text{pH}_m = (7.6 \pm 0.1)$  for 20 days. The spectra of the references for Pu(IV)<sub>aq</sub> (red line) and Pu(III)<sub>aq</sub> (blue line) reported in Brendebach et al.<sup>8</sup> are shown for comparison.

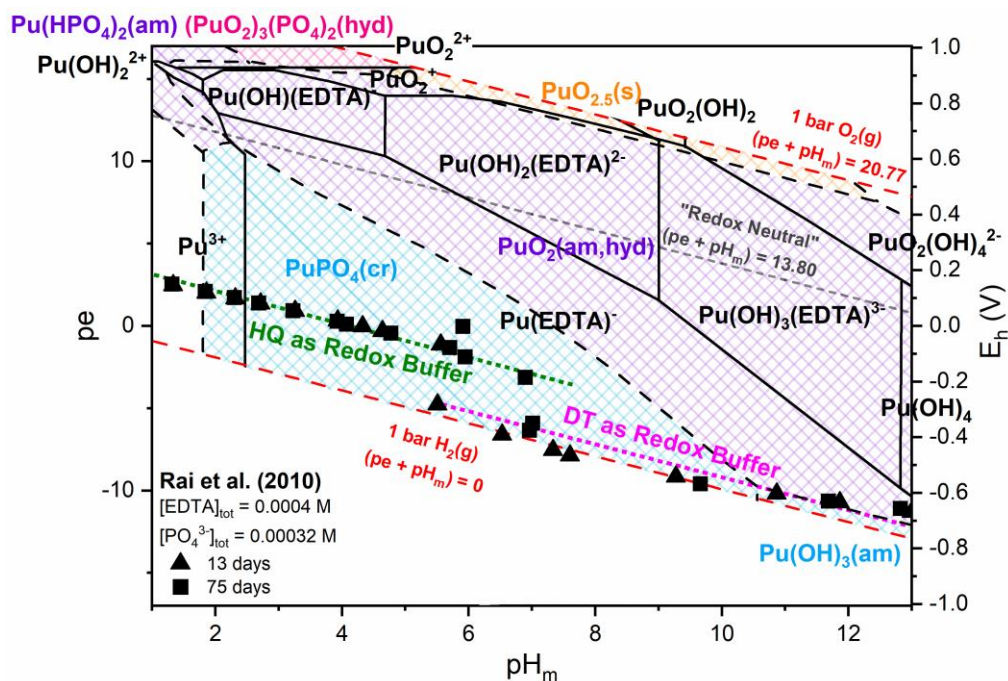

Figure S3. Pourbaix diagram of the Pu-PO<sub>4</sub>-EDTA system at [Pu] = 1.0 mM, [PO<sub>4</sub><sup>3-</sup>] = 0.00032 M, [EDTA] = 0.0004 M, and I = 0.1 M calculated from values in Tables S1 and S2 with experimental pH<sub>m</sub> and pe measurements from Rai et al.<sup>4</sup> Solid black lines correspond to redox borderlines between aqueous plutonium species and dashed black lines represent redox borderlines between solid plutonium compounds. Dotted lines correspond to the redox conditions for experiments in which hydroquinone (HQ, green) or dithionite (DT, pink) were used as redox buffers.

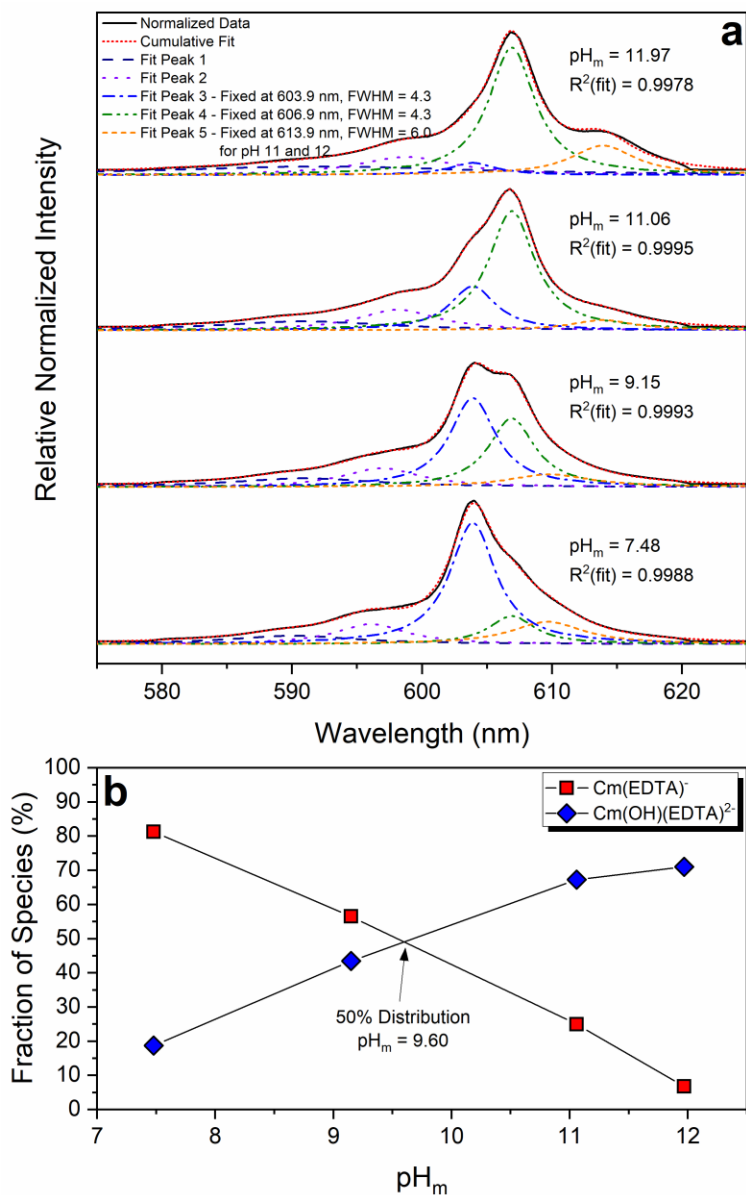

Figure S4. (a) Peak fitting results of laser fluorescence spectra of curium ( $[\text{Cm}] = 10^{-7} \text{ M}$ ) equilibrated in solutions containing  $[\text{EDTA}]_{\text{tot}} = 1 \text{ mM}$  and  $I = 0.1$  as a function of  $pH_m$ . (b) Fraction of Cm-EDTA species calculated from peak fitting integrated peak areas as a function of  $pH_m$ .

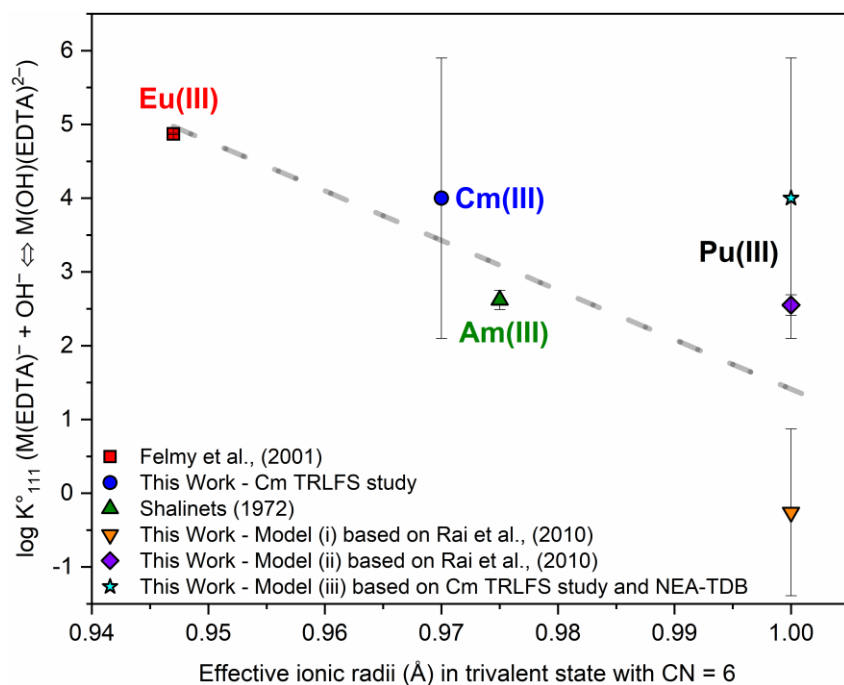

Figure S5. Linear free energy relationship between the step-wise formation constants:  $\log K^{\circ}_{111}$  for trivalent lanthanide- and actinide-EDTA complexes with  $\text{OH}^-$  ion derived within this work or adapted from the literature<sup>10,11</sup> as plotted against the effective ionic radii (Å) of the trivalent metal ions at a coordination number (CN) of 6. The gray dashed line represents the anticipated trend along the series.

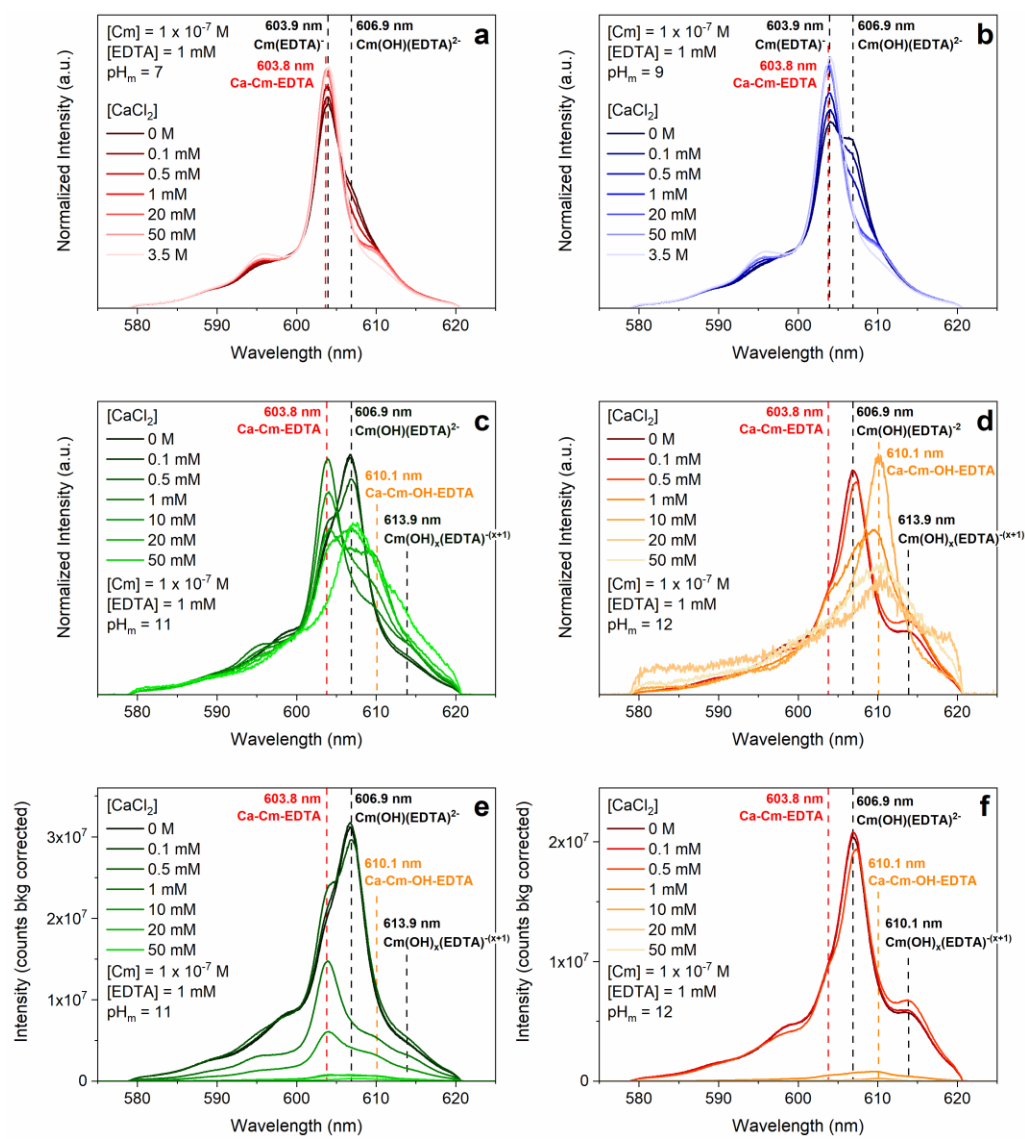

Figure S6. Laser fluorescence spectra of curium ( $[Cm] = 10^{-7} M$ ) equilibrated in solutions containing  $[EDTA]_{tot} = 1 mM$  and  $I = 0.1$  or  $10.5 M$  as a function of calcium concentration ( $0 M \leq [CaCl_2] \leq 3.5 M$ ) represented as either spectra with intensity normalized by the sum area or background corrected intensity: (a)  $pH_m = 7$  normalized spectra, (b)  $pH_m = 9$  normalized spectra, (c)  $pH_m = 11$  normalized spectra, (d)  $pH_m = 12$  normalized spectra, (e)  $pH_m = 11$  background corrected intensity spectra, and (f)  $pH_m = 12$  background corrected intensity spectra. Cm-EDTA peak positions are identified by black dashed vertical lines and Ca-Cm-EDTA peak positions are identified by colored dashed vertical lines.

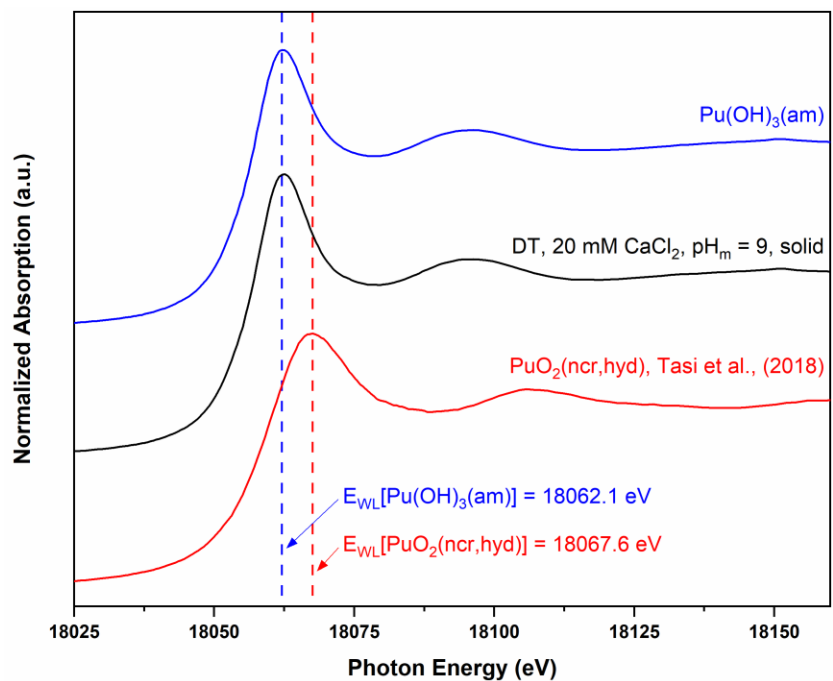

Figure S7. Pu L<sub>III</sub>-edge XANES spectra measured *in-situ* for Pu(OH)<sub>3</sub>(am) equilibrated with dithionite (DT), 1 mM EDTA, 20 mM CaCl<sub>2</sub>, and  $I = 0.1$  M at pH<sub>m</sub> = (9.0 ± 0.1) for 20 days. The spectra of the reference PuO<sub>2</sub>(ncr,hyd) solid phase (red line) reported in Tasi et al.,<sup>9</sup> and freshly synthesized Pu(OH)<sub>3</sub>(am) solid phase (blue line) are shown for comparison.

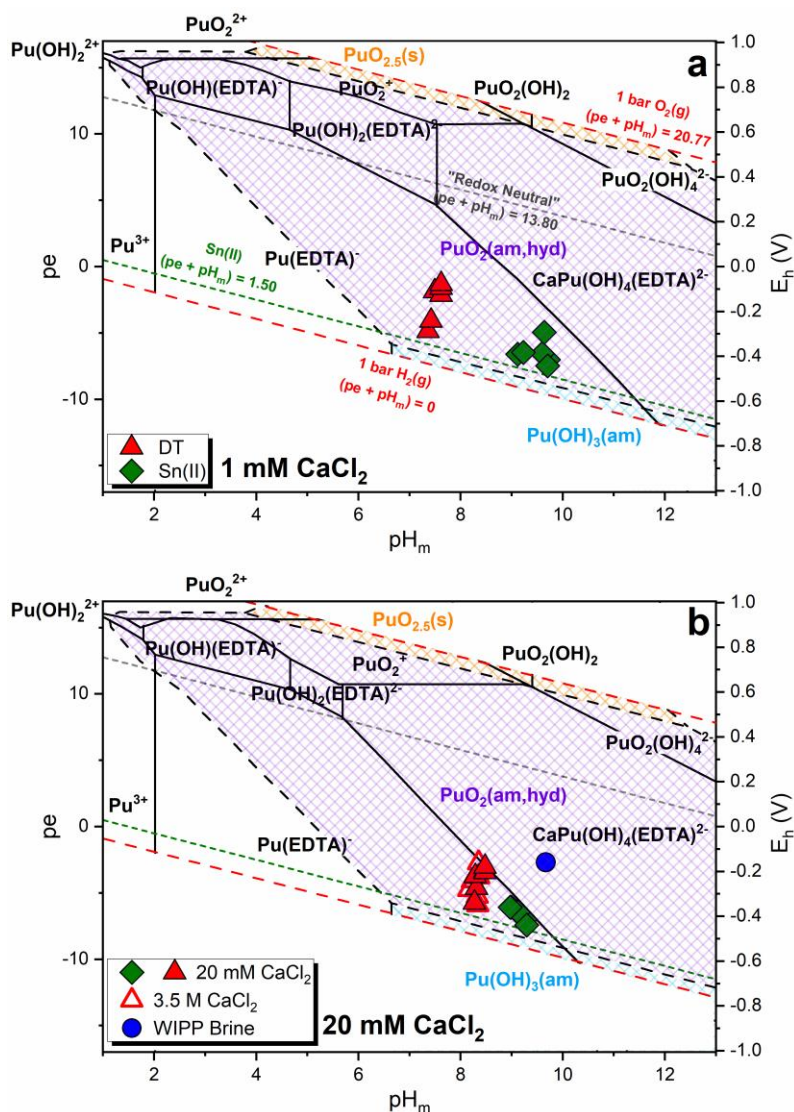

Figure S8. Pourbaix diagrams of the Pu-EDTA system at  $[Pu] = 1.1 \text{ mM}$ ,  $[EDTA] = 1 \text{ mM}$ ,  $I = 0.1 \text{ M}$ , and (a)  $1 \text{ mM CaCl}_2$  or (b)  $20 \text{ mM CaCl}_2$  calculated from values in Tables S1 and S2. Experimental  $pH_m$  and  $pe$  measurements are shown for experiments conducted in the presence of Sn(II) (solid green diamonds), in the presence of dithionite (DT) with 0–20 mM  $\text{CaCl}_2$  (solid red triangles), in the presence of DT with 3.5 M  $\text{CaCl}_2$  (open red triangles), and in the absence of any redox buffer in the simulated WIPP brine (solid blue circles). Solid black lines correspond to redox borderlines between aqueous plutonium species and dashed black lines represent redox borderlines between solid plutonium compounds.

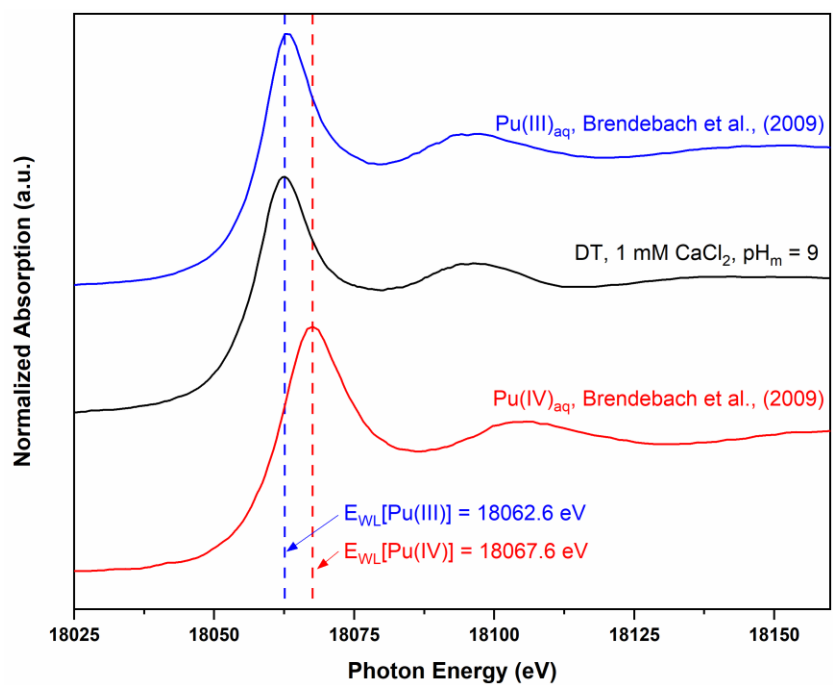

Figure S9. Pu L<sub>III</sub> XANES spectra measured *in-situ* for the aqueous phase of Pu(OH)<sub>3</sub>(am) equilibrated with 1 mM EDTA, 1 mM CaCl<sub>2</sub>, and  $I = 0.1$  M for 20 days. The spectra of the references for Pu(IV)<sub>aq</sub> (red lines) and Pu(III)<sub>aq</sub> (blue lines) reported in Brendebach et al.<sup>8</sup> are shown for comparison.
