1. General Information

Materials and spectroscopic methods. Cu salts were purchased from Sigma Aldrich. Benzylic C–H substrates and the reagents for the syntheses were purchased from Oakwood Chemicals, Combi-Blocks, Chem-Impex, Alfa Aesar, TCI America, Ark Pharm, Enamine, AstaTech or Sigma Aldrich, and were used without further purification. TMSNCO was purchased from TCI America. Ligands were purchased from Aldrich or TCI America. *N*-fluorobenzenesulfonimide (NFSI) was purchased from Ark Pharm. The solvents were purchased from Fisher Scientific or Sigma Aldrich. The silica gel (particle size 40–63 μm , 230–400 mesh) that was used for flash column chromatography and thin layer chromatography plates (250 μm thickness) were purchased from SiliCycle. Chromatography was conducted using Biotage Isolera One® with reusable 60 or 120 g SNAP Ultra® C18 cartridges. The ^1H NMR, ^{13}C NMR, and ^{19}F NMR spectra were recorded on a Bruker 400, 500, or 600 MHz spectrometer. High-resolution mass spectra were obtained using a Thermo Q Exactive™ Plus by the mass spectrometry facility at the University of Wisconsin–Madison. IR spectra were recorded on a Bruker Platinum-ATR ALPHA spectrometer. Melting points were determined using a DigiMelt MPA160 SRS melting point apparatus. Enantioselectivities were determined by SFC/MS analyses on a Waters TharInvestigator equipped with a Daicel CHIRALCEL® OD-H HPLC analytical column (particle size 5 μm , ID 4.6 mm x L 250 mm).

2. General Procedure for Cu-Catalyzed Benzylic C–H Isocyanation

Procedure A: A 4 mL borosilicate glass vial was charged with benzylic substrate (0.4 mmol), 2.0 mol% of copper(I) acetate (1.0 mg, 8.0 μmol), 2.0 mol% of 2,2'-bis(2-oxazoline) (1.1 mg, 8.0 μmol), 2.5 equivalents of *N*-fluorobenzenesulfonimide (315 mg, 1.00 mmol), and a magnetic stir bar outside a glovebox. The vial was capped with an open-top cap installed with a PTFE lined silicone septum. The septum cap was pierced by a needle and the vial was moved into the glovebox and underwent four cycles of vacuum-nitrogen-backfill over 40 minutes. After removal of the needle, the vial was removed from the glovebox. The vial was charged with acetonitrile (3.3 mL, 0.12 M), 3.0 equivalents of (trimethylsilyl)isocyanate (160 μL , 1.2 mmol), 0.5 equivalents of diisopropyl phosphite (33 μL , 0.2 mmol) sequentially, stirred, and heated to 30 °C (inner temperature) in a heating block on a hot plate. After 20 hours, the vial was cooled to room temperature (25 °C) for urea formation reaction without any workup.

Procedure B: Adopting Procedure A, the reaction was performed for 2 hours.

Procedure C: Adopting Procedure A, the reaction was performed at 25 °C for 2 hours.

Procedure D: Adopting Procedure A, the reaction was performed at 40 °C for 20 hours. Deviation from Procedure A was 6.0 mol% of copper(I) acetate (2.9 mg, 24 μmol), 6.0 mol% of 2,2'-bis(2-oxazoline) (3.4 mg, 24 μmol).

Procedure E: Adopting Procedure D, the reaction was performed at 30 °C for 20 hours.

Procedure F: Adopting Procedure A, the reaction was performed at 30 °C for 20 hours. Deviation from Procedure A was 10 mol% of copper(I) acetate (4.9 mg, 40 μmol), 10 mol% of 2,2'-bis(2-oxazoline) (5.6 mg, 40 μmol).

Notes:

- (1) Calibration of hot plate is highly recommended to maintain inner reaction temperature because performance of this reaction is sensitive to temperature.
- (2) Liquid benzylic C–H substrates were added between addition of acetonitrile and (trimethylsilyl)isocyanate.
- (3) Hamilton glass syringe was used for the addition of (trimethylsilyl)isocyanate which is sensitive to plastics.
- (4) Diisopropyl phosphite was stored in glovebox.

3. General Procedure for Urea Formation

Following isocyanation, an 8 mL borosilicate glass vial was equipped with a magnetic stir bar and capped with an open-top cap containing a PTFE-lined silicone septum. The septum was then pierced with a needle before moving the vial into the small antechamber of the glovebox. Three cycles of vacuum-nitrogen backfill were performed and the vial was placed inside the glovebox. The needle was then detached from the cap and the sealed vial was subsequently removed from the glovebox. Afterwards, the vial was charged with 5 equivalents of *m*-anisidine (225 μ L, 2 mmol) and placed on a heating block set at 50°C and stirring. The 4 mL vial containing the isocyanate crude mixture was pierced with a needle attached to a nitrogen-filled balloon. Then, a syringe was used to draw the isocyanate crude mixture. Following this, a needle connected to a nitrogen-filled balloon was used to puncture the 8 mL reaction vial charged with *m*-anisidine before the slow addition of the isocyanate crude mixture. The 4 mL vial containing the isocyanate crude mixture was rinsed three times with 300 μ L of acetonitrile, and each rinse was added to the 8mL vial. After 20 hours of urea formation, the reaction mixture was cooled to room temperature and the purification procedure involved direct subjection to a reverse-phase column on Biotage, which used a gradient deionized H₂O:CH₃CN (2:3) elution.

4. Computational Methods for Calculation of Molecular Properties

The calculations of the physicochemical properties were performed using the method described by Tan *et al.*¹ The SMILES code of all coupling amines and corresponding ureas were generated from the structures drawn in ChemDraw. The SMILES codes were copied into an MS Excel document before saving the file as a tab delimited .txt file. The text file containing the codes was imported into Instant JChem and the physicochemical properties (clogP, hydrogen bond donors, hydrogen bond acceptors, number of rotatable bonds, molecular weight, and topological polar surface area) were calculated using the New Chemical Term Field function. Following the calculations, the structures and physicochemical properties were exported from Instant JChem as the Excel spreadsheet (.XLSX).

SFC/MS analyses were conducted on a Waters TharInvestigator equipped with a Daicel CHIRALCEL® OD-H HPLC analytical column (particle size 5 μm, ID 4.6 mm x L 250 mm) was used for separations of enantiomers. The samples were eluted with MeOH 20% with CO₂ at a flow rate of 3 mL/min at 35 °C with an automated backpressure regulator at 100 bar. Injection volume for each sample was 5.0 μL of a 10-30 μM solution in acetonitrile and the detection wavelength was 273 nm.

6. Limitation of C–H Isocyanation

Table S11. Unsuccessful C–H Substrates

Isocyanation of some substrates were not successful. Electron-rich (Table S11A) and electron-deficient (Table S11B) gave low yields. Even though the reactions with both thiophene and furan substrates showed excellent conversion, but the yields were low-to-no yield (Table S11C). The *N*-heterobenzylic substrates embedding isoxazole, pyrazole, tetrazole, pyrazolopyrimidine, and benzopyrrole rings afforded low-to-no yield (Table S11D).

7. Experimental Details for High Throughput Synthesis of Benzylic Ureas

High-Throughput Experiment Procedure of Isocyanation/Urea Formation

All reagents were used as purchased from commercial suppliers. Solvents were purchased from Sigma-Aldrich, anhydrous, sure-seal quality, and used with no further purification. The reagents and catalysts were purchased from commercial sources and stored in the glovebox. All reactions were performed inside an MBraun glovebox operating with a constant nitrogen purge (oxygen typically < 5 ppm) unless otherwise noted. Liquid handling was done using single and multi-channel Eppendorf pipettors (10, 100, 200, and 1000 μ L).

A 24 mL borosilicate glass vial was charged with benzylic substrate (1.3 mmol for **1s** and **1t**), 2.0 mol% of copper(I) acetate (3.2 mg, 26 μ mol), 2.0 mol% of 2,2'-bis(2-oxazoline) (3.6 mg, 26 μ mol), 2.5 equivalents of *N*-fluorobenzenesulfonimide (0.103 g, 3.25 mmol), and a magnetic stir bar outside a glovebox. [For the substrate **1u**, 10 mol% of copper(I) acetate (15.9 mg, 0.13 mmol), 10 mol% of 4,4',5,5'-tetrahydro-2,2'-bi-1,3-oxazole (18.2 mg, 0.13 mmol) were used.] The vial was capped with an open-top cap installed with a PTFE lined silicone SURE-LINKTM septum. The septum cap was pierced by a needle (22 gauge - 1 1/2", 0.7 mm x 40 mm). The vial (having the needle on top) was moved into the glovebox antechamber and underwent four cycles of vacuum-nitrogen-backfill over 20 minutes, and then the vial is moved into the glovebox. After removal of the needle and cap, the vial was charged with acetonitrile (12.5 mL), diisopropyl phosphite (33 μ L, 0.2 mmol), and 3.0 equivalents of (trimethylsilyl)isocyanate (160 μ L, 1.2 mmol) sequentially, stirred, and heated to 30 °C (for the substrates **1u**) for 20 hours in a heating block on a hot plate. For the substrates **1s** and **1t**, the reaction was conducted at 25 °C for 2 h. [Note: Glass pipette or glass syringe/plunger should be used to transfer (trimethylsilyl)isocyanate. (trimethylsilyl)isocyanate reacts with plastics, forms a white powder (maybe polymer), and drops the reaction yield.]

2.0 mL of acetonitrile was added to each vial having 2.0 mmol of amine. All vials were sonicated vigorously at an acceleration of 10G (G is the acceleration of gravity; 9.81 m/s²) for 2 hours in Resodyn acoustic mixing LabRam (PharmaRAM II Mixer). 0.05 mL of each 1.0 M amine in acetonitrile was dispensed to 250 μ L microvials (Analytical Sales, Cat. No. 10421) containing a stir bar in 96-well reaction microplates (Analytical-Sales, Cat. No. 24250). Using a multichannel pipette, 0.1 mL of the crude isocyanate solution (0.01 mmol) was added to each vial containing amine outside the glove box (Note: The exposure of the crude isocyanate solution to moisture should be minimized). On completion of solution dosing, the plates were covered by a perfluoroalkoxy alkane (PFA) mat (Analytical-Sales, Cat. No. 96967 and 24261), followed by two silicon rubber mats (Analytical-Sales, Cat. No. 96965 and 24262), and an aluminum cover which was tightly and evenly sealed by 9 screws. The sealed plates were put inside the glovebox, opened, purged with N₂ for 30 seconds, covered again, and stirred at 35 °C.

After 20 hours, the plate was removed from the glovebox. 0.2 mL of DMSO was added to each well and mixed on the plate. 0.02 mL of each reaction mixture was taken and filtered through a Millipore multiscreen-solviret filter plate (0.45 μ M low binding hydrophilic PTFE MSRLN0450) to a shallow 96-well storage plate (Corning) and rinsed the filter twice with 0.09 mL of DMSO. The 96-well storage plate having the analytes was sealed and injected to Waters UPLC-MS instrument.

Reactions were monitored using a Waters Acquity UPLC I-Class system (Waters Corp., Milford, MA, USA) equipped with a binary pump, a FTN sampler, column manager, a photodiode array detector, SQD detector 2 with electrospray ionization (ESI) source in the positive mode and MassLynx® software. Waters CORTECS UPLC C18+ column ($30 \times 2.1\text{mm}$, $1.6\mu\text{m}$) was used for peak separation.

High throughput data analysis was done with Virscidian Analytical Studio™ software. Conversion to product was analyzed by UPLC-UV. Area percents of product, remaining starting material and side product peaks at 210 nm were calculated. The reactions were analyzed by molecular weights of products, anticipated side products, and reactants. The protocol for this analysis was shown with an example in Figure S2 and S3. 9. Characterization Data

1-(6-(*tert*-butyl)-3-isocyanato-1,1-dimethyl-2,3-dihydro-1*H*-inden-4-yl)ethan-1-one (2t): Prepared from celestolide (**1t**) according to Procedure C. The reaction mixture was purified by flash column chromatography (ethyl acetate:pentane = 1:20) to afford **2t**.

Note: (1) Flash column chromatography was performed within 15 minutes since the isocyanate reacts with silica gels and it could lead to low isolated yield. (2) Evaporation of solvents on rotovap was carefully conducted due to the volatility of **2t**. To measure the exact isolated yield, rigorous repeating distillations are recommended. In this experiment, further distillation was not performed, but the mass of **2t** was calibrated by offsetting that of remaining ethyl acetate on ¹H NMR spectrum.

NMR Yield: 66%

Isolated Yield: 51% (58.0 mg)

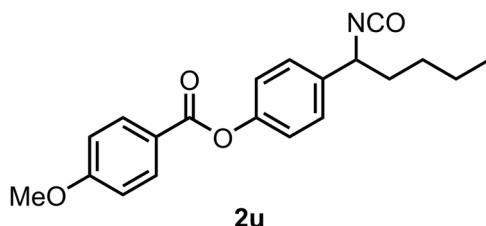

Physical Property: Colorless oil.

Note: The isocyanate **2u** is sensitive to silica gels. See the note for the preparation of **2t**.
