## 1. Materials and general methods

Unless specifically stated, all chemical reagents were used of the highest available quality and were used directly without further purification or distillation. XL413 was purchased from MedChemExpress (USA). All solvents and inorganic salts were analytical grade unless otherwise noted. Distilled water was used for all experiments. Analytical thin-layer chromatography (TLC) used commercial silica gel plates (GF254). Flash column chromatography was performed using Merck silica gel (200-300 mesh). The composition of mixed solvents is given by the volume ratio ( $\mathrm{v} / \mathrm{v}$ ). The ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were acquired on a Varian Unity INOVA-400 spectrometer, Bruker 400, Bruker 600 instruments and JEOL spectrometer operating at 400 MHz . High-resolution mass spectra (HRMS) were performed with a Bruker micro-TOF-QII mass spectrometer (Bruker Daltonics Corp, Germany) in electrospray ionization (ESI) mode. The single crystal structures were determined by X-ray crystallography with a Bruker SMART APEX-CCD system and a Bruker VEBTURE system. The pictures of solid powders were taken on Nikon SMZ18 solid microscope. Absolute fluorescence quantum yields were measured using the Absolute PL quantum yield spectrometer C9920-02G (Hamamatsu). The pH measurements were carried out on a Mettler Toledo pH meter. The refractive indices were measured using the abbe refractometer (INESA WYA, China). The fluorescence spectra were measured with a Hitachi F-2700 fluorescence spectrophotometer (Tokyo, Japan) with a 10 mm quartz cuvette. The UV-visible absorption spectra were determined by a MAPADA UV-1800 spectrophotometer with a 10 mm quartz cuvette. Fluorescence imaging studies of cells were observed using a confocal laser scanning microscope (Nikon Alplus, Japan) with excitation wavelength at 488 nm and 561 nm . Fluorescence imaging studies of C. elegans were recorded using a confocal laser scanning microscope (Leica TCS SP8) with excitation wavelength at 488 nm and 561 nm .

## X-ray crystallography details

The single crystal of ROB was obtained by diffusion method and the crystal was purple and transparent. The single crystals of ROCL, ROCZ and ROE were grown from a mixture of ethanol and dichloromethane by volatilization method and the crystals were colourless and transparent. The single crystals of ROKS and ROZ were obtained by diffusion method and the crystals were yellow and transparent. Single-crystal X-ray experiments were performed using a Bruker Smart Apex CCD diffractometer equipped with a graphite-monochromatized Mo K $\alpha$ radiation $(\lambda=0.71073 \AA)$ using $\omega$ and $\varphi$ scan mode at room temperature and a Bruker VENTURE system with a Ga-target liquid METALJET D2 PLUS X-ray Source ( $\lambda=1.34139$ $\AA$ ) at 174 K . The data integration and reduction were processed with SAINT software. The structures were solved by the direct method using SHELXS and refined by a full-matrix least-
squares method on F2 with the SHELXL-2014 program. ${ }^{1,2}$ Hydrogen atoms were placed in geometrically calculated positions. A summary of the crystallographic data and the structure refinement parameters of ROB, ROCL, ROCZ, ROE, ROKS and ROZ are given in Table S2-S3, respectively. The crystallographic data for ROB, ROCL, ROCZ, ROE, ROKS and ROZ can be found in the CCDC with the numbers 2018837, 2018838, 2018841, 2018842, 2018843 and 2018844.

## Preparation of UV-Vis and fluorescence spectral measurements

ROKS, ROCL, ROB, ROE, ROCZ and ROZ were dissolved in analytical grade DMF to obtain stock solutions ( 1 mM ), respectively. The stock solution of thiophenol ( 10 mM ) were prepared in analytical grade DMF. The stock solution of various ROS including $\mathrm{HOCl}, \mathrm{O}_{2}{ }^{-}$, NO, TBHP, $\mathrm{H}_{2} \mathrm{O}_{2},{ }^{\circ} \mathrm{OH},{ }^{1} \mathrm{O}_{2}, \mathrm{TBO}^{\cdot}$ and $\mathrm{ONOO}^{-}$were prepared according to previous reports. ${ }^{3,4}$ The stock solutions of various ions $(1 \mathrm{mM})$ including $\mathrm{Fe}^{3+}, \mathrm{Al}^{3+}, \mathrm{Zn}^{2+}, \mathrm{Mg}^{2+}, \mathrm{HSO}_{3}{ }^{-}$, $\mathrm{HSO}_{4}^{-}, \mathrm{S}_{2} \mathrm{O}_{3^{-}}{ }^{--}, \mathrm{SCN}^{-}, \mathrm{NO}_{2}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{HCO}_{3^{-}}{ }^{-}, \mathrm{CO}_{3}{ }^{2-}, \mathrm{F}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}$and $\mathrm{I}^{-}$were prepared by direct dissolution of corresponding salt in distilled water. Small biological molecules (Cys, Hcy and GSH) were dissolved in distilled water to obtain stock solutions ( 1 mM ).

## Measurement of relative fluorescence quantum yields

The relative fluorescence quantum yield of compound ROB was determined in PBS buffer solution ( $10 \mathrm{mM}, \mathrm{pH}=7.4$, containing $10 \%$ DMF) using Rhodamine B as a reference with a known $\Phi$ value of 0.89 in ethylene glycol excited at $535 \mathrm{~nm} .{ }^{5}$ The relative fluorescence quantum yields of compounds ROCL, ROCZ and ROE were determined in PBS buffer solution ( $10 \mathrm{mM}, \mathrm{pH}=7.4$, containing $10 \% \mathrm{DMF}$ ) using quinine sulfate as a reference with a known $\Phi$ value of 0.55 in $0.1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ excited at $365 \mathrm{~nm} .{ }^{6}$ The relative fluorescence quantum yields of compounds were calculated following the equation (1):

$$
\begin{equation*}
\Phi_{S} / \Phi_{R}=\left(F_{S} / F_{R}\right) \times\left(A_{R} / A_{S}\right) \times\left(\eta s^{2} / \eta_{R}^{2}\right) \tag{1}
\end{equation*}
$$

Where $S$ and $R$ are the sample and the reference, respectively. $\Phi$ is the fluorescence quantum yield. $F$ is the relative integrated fluorescence emission area. $A$ is the absorbance at the excitation wavelength. $\eta$ is the refractive index of the solvent. The refractive indices of ethylene glycol, $\mathrm{H}_{2} \mathrm{SO}_{4}(0.1 \mathrm{M})$ and PBS buffer solution $(10 \mathrm{mM}, \mathrm{pH}=7.4$, containing $10 \%$ DMF) were measured respectively to be $1.4274,1.3335$ and 1.3463 by abbe refractometer (INESA WYA, China).

## Measurement of absolute fluorescence quantum yields

The absolute fluorescence quantum yields of compounds in solid form were determined by the Absolute PL quantum yield spectrometer C9920-02G.

## Determination of detection limit

The limit of detection (LOD) was determined from the fluorescence titration data. According to the results of the titrating experiment, a good linear relationship between the fluorescence intensity and the determinand concentration was obtained. The detection limit was calculated by means of equation (2):

$$
\begin{equation*}
\mathrm{LOD}=3 \sigma / \mathrm{K} \tag{2}
\end{equation*}
$$

Where $\sigma$ is the standard deviation of the blank measurement and $K$ is the slope of the calibration curve.

## Density functional theory calculations

Gaussian 09 program at $\omega \mathrm{B} 97 \mathrm{X}-\mathrm{D} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory was employed to optimize the ground state (GS) of 1.3-dinitrobenzene and the triplet state of ROCL, and then the orbital energies were calculated. ${ }^{7,8}$ To mimic the d-PeT process, 1.3-dinitrobenzene was calculated using the GS where the LUMO orbital was occupied by an electron pair. However, ROCL was calculated using the triplet state in which each HOMO and LUMO were occupied by a single electron, respectively.

## Cell culture

The HepG2 cells line were obtained from Procell Life Science \& Technology Co., Ltd (Wuhan, China). The HepG2 cells were cultured in Dulbecco's modified Eagle's medium (DMEM) containing 10\% fetal bovine serum (FBS). The HepG2 cells were seeded at a density of $1 \times 10^{5}$ cells per dish and cultured in a humidified atmosphere of $5 \% \mathrm{CO}_{2}$ and $95 \%$ air at $37^{\circ} \mathrm{C}$. For senescence induction, HepG2 cells were supplemented with media including XL413 ( $5 \mu \mathrm{M}$ ) for different times ( 3 days and 5 days). For cell fixation, HepG2 cells were added with $4 \%$ paraformaldehyde and incubated for 10 min .

## Cytotoxicity assay

The cytotoxicity of ROKS to HepG2, MRC-5, HL-7702, Hela and A549 cells and ROCL to HepG2 cells was assessed by performing standard Cell Counting Kit-8 (CCK-8) assay. ${ }^{9}$ cells ( $5 \times 10^{3}$ cells/well) were seeded into 96-well plates in DMEM medium containing $10 \% \mathrm{FBS}$ and cultured at $37{ }^{\circ} \mathrm{C}$ under $5 \% \mathrm{CO}_{2}$ for 24 h . Different concentrations of ROKS and ROCL $(0,10,20,30,40$ and $50 \mu \mathrm{M})$ were added to the wells. After incubation for $24 \mathrm{~h}, 100 \mu \mathrm{~L}$ CCK-8 solution ( $10 \%$ in serum free culture medium) was added to each well, and the plate was incubated for another 2 h . The absorbance of each well at 450 nm were measured by a microplate reader, and then the viability of cells was calculated using equation (3):

$$
\begin{equation*}
\text { cell viability }=\left(\mathrm{OD}_{\text {positive }}-\mathrm{OD}_{\text {control }}\right) /\left(\mathrm{OD}_{\text {negtive }}-\mathrm{OD}_{\text {control }}\right) \tag{3}
\end{equation*}
$$

## Western blot analysis

HepG2 cells were incubated with XL413 (5 $\mu \mathrm{M}$ ) under $5 \% \mathrm{CO}_{2}$ in air and humidified atmosphere at $37^{\circ} \mathrm{C}$ for 3 days. Then the XL413-incubated cells were washed with PBS three times, removed from plates and dipped in RIPA buffer that contain protease inhibitor. The concentration of proteins was determined using a BCA proteins assay kit. Protein samples were mixed with SDS-PAGE loading buffer and were heated for 10 min at $100{ }^{\circ} \mathrm{C}$ to fully denature the proteins. A $10 \%$ SDS-PAGE gel was used to separate the proteins, followed by transfer onto a PVDF membrane at 300 mA for 2 h to measure the expression level of the targeted proteins. $5 \%$ skim milk in $0.1 \%$ tris buffered/tween 20 (TBST) were utilized to block membrane for one hour at room temperature and the membrane were incubated along with antibodies ( $\gamma$-H2AX: Abcam, ab81299, 1/10000 dilution; GAPDH: Abclonal, ac033, $1 / 2000$ dilution) at $4^{\circ} \mathrm{C}$ for 12 h . Finally, the membrane was washed with TBST and further incubated with secondary antibodies (Anti-rabbit IgG antibody, CST, 7074P2; Goat antiMouse IgG antibody, Arigo, ARG65350) for 1 h and then chemiluminescence enhancement method was used to check protein's signal. Tanon-4600SF image-capturing system was utilized to image the gels.

## X-gal staining assay

X-gal staining was performed according to the X-gal staining kit protocols (Beyotime Biotechnology). The HepG2 cells pre-incubated with XL413 ( $5 \mu \mathrm{M}$ ) for 5 days were cultured at $37^{\circ} \mathrm{C}$ and then fixed with $4 \%$ paraformaldehyde for 10 min . Subsequently, the HepG2 cells were treated with X-gal solution ( $1 \mathrm{mg} / \mathrm{mL}$ ) and cultured at $37^{\circ} \mathrm{C}$ overnight. After that, the HepG2 cells were washed by PBS buffer solution for three times and the change of blue color was observed under an inverted microscope.

## C. elegans culture and imaging

C. elegans were grown and maintained on nematode growth medium (NGM) agar plates at $20^{\circ} \mathrm{C}$. They were fed Escherichia coli strain OP50 (Escherichia coli) and cultured under standard conditions until the worms reached the young adult, then picked the worms which were cultured for 6 days and 12 days to the next experiment. The $C$. elegans were incubated with ROKS $(30 \mu \mathrm{M})$ in centrifuge tubes for 60 min and treated with $\mathrm{PhSH}(3 \mu \mathrm{M})$ for different times $(0,15,30,45$ and 60 min$)$, then picked for imaging.
