

Interaction of anions with the surface of a coordination cage in aqueous solution probed by their effect on a cage-catalysed Kemp elimination

Michael D. Ludden, Christopher G. P. Taylor, Max B. Tipping, Jennifer S. Train, Nicholas H. Williams, Jack C. Dorrat, Kellie L. Tuck and Michael D. Ward

Supporting Information

1. Characterisation of the cage H^W
2. UV/vis data for control experiments
3. UV/vis data for anion addition experiments
4. UV/vis data for anions of varying basicity experiments
5. Additional figures

1. Characterisation of the cage $\mathbf{H^W}$

The cage $\mathbf{H^W}$ was prepared following a previously described procedure.^{S1} After dissolution in deionised water, samples of $\mathbf{H^W}$ were filtered using a 0.2 μm Millipore filter to remove any solid particulates. The pH of the cage solution was then adjusted to pH 7 through addition of 1 M NaOH solution.

To confirm the stability of the cage in aqueous solution, a combination of paramagnetic ^1H NMR spectroscopy and electrospray mass spectrometry were used. The spectrum of $\mathbf{H^W}$ (0.2 mM, D_2O) is shown below (Figure S1).^{S1} This corresponds to known spectra of the cage and confirms its formation in solution. ESI-MS results also corroborated these findings, with signals for $\mathbf{H^W}$ corresponding to loss of 7 or 8 tetrafluoroborate anions, $[\mathbf{H^W} - 7\text{BF}_4]^{7+}$ and $[\mathbf{H^W} - 8\text{BF}_4]^{8+}$ state being apparent.

Figure S1 – ^1H NMR spectrum of the cage $\mathbf{H^W}$ recorded in D_2O after dissolution and subsequent filtration. T = 298 K.

2. UV/vis spectroscopic data for control experiments

2.1. Data Manipulation

From the UV/vis spectroscopy plate-reader data, values for k_{cat} and k_2 were calculated using initial rates. To do this, the absorbance at a chosen wavelength was monitored over time, with the data being recorded typically every 120 seconds for 4h, with the first 20 points being used. The wavelength chosen depends on whether the product, 2-cyano-4-nitrophenolate, is bound to the exterior of H^{W} , as this induces a red-shift in the absorption spectrum (see main text). Two examples of spectra are given below, one with H^{W} present and one without.

For any reactions monitored over time by UV/vis, the rate was determined through monitoring the absorbance of the product 2-cyano-4-nitrophenolate at its absorption maximum, which varies depending on the concentration of H^{W} . The extinction coefficient quoted in the literature is $15,800 \text{ M}^{-1} \text{ cm}^{-1}$ (reference S2) and using this a concentration of product could be calculated from the absorbance. Each dataset was corrected by first setting the absorbance at $t = 0 \text{ s}$ to equal zero, followed by subtracting the background absorbance from the uncatalysed reaction under the same conditions at each data point to give the catalysed reaction profile. Taking the natural log of the concentration of starting material and using the LINEST function in Excel, a rate constant could be determined for each dataset along with the standard error for the data. This analysis function was typically used over the first 20 datapoints, giving an initial rate. Each set of values for absorbance was an average of 4 repeats.

A summary of the experiments covered in Section 2 of this Supporting Information is provided below. As described above, values for k_{cat} and the SE of k_{cat} were obtained using the LINEST function and are provided for each dataset.

Sample	Sample name	λ_{max}	$[\text{H}^{\text{W}}] / \mu\text{M}$	$k_{\text{cat}} / \text{s}^{-1}$	SE of k_{cat}	% error	$k_2 / \text{M}^{-1} \text{s}^{-1}$

5. Additional figures

Figure S2. Energy-minimised structure of the cage/NBI 1:1 complex obtained using GOLD (see main text). The NBI was posed initially in four different orientations and all converged to the same minimum-energy structure (see four overlays).

Figure S3. Rate of cage-catalysed reaction (Kemp elimination with NBI) using cage alone (red data points) and then after addition of sufficient cyclundecanone to block the cage cavity (black data points) – showing virtually no change from blocking the cavity. For reference the rate of the uncatalysed background reaction is shown with blue data points.
