## 1. Experimental methods

Chemicals. The synthetic procedures of AF (2-[(3,4-(bis(esiloxy)-phenylethynyl),7-(4-aldehyde-phenylethynyl)] fluorene) and NF (2-[(3,4-(bis(dodeciloxy)-phenylethynyl),7-(4-nitro-phenylethynyl)] fluorene) compounds had been already described in a previous paper. ${ }^{1}$ For compound $\mathbf{F}$ (2,7-bis[3,4-bis(dodeciloxy)-phenylethynyl] fluorene) the synthesis is reported below in the dedicated paragraph.

Spectral and photophysical characterizations were performed in several solvents of spectroscopic grade: cyclohexane (CH, VWR Chemicals), methyl cyclohexane (MC, ACS Reagent, Sigma-Aldrich), 3-methyl pentane (3MP, Acros Organics), toluene (Tol, ACS Reagent, Sigma-Aldrich), ethyl acetate (EtAc, AnalaR, BDH), dicholoromethane (DCM, Carlo Erba Reagents), dimethylformamide (DMF, ACS Reagent, Sigma-Aldrich) and acetonitrile (MeCN, VWR Chemicals).

Photophysical measurements. Absorption spectra of solutions ( $\approx 1 \times 10^{-5} \mathrm{M}$ ) were recorded by using a Cary 4E (Varian) spectrophotometer. Fluorescence and excitation spectra were instead detected by a FluoroMax-4P spectrofluorimeter (HORIBA Scientific) and manipulated by FluorEssence software with the appropriate instrumental response corrections. The fluorescence quantum yields ( $\Phi_{\mathrm{F}}$, experimental error $\pm 10 \%$ and $\pm 20 \%$ when $\Phi_{\mathrm{F}}<10^{-4}$ ) of dilute solutions ( $1 \times 10^{-6}$ M) were obtained exciting each sample at the relative maximum absorption wavelength by employing 9,10diphenylanthracene ( $\Phi_{\mathrm{F}}=0.73$ in air-equilibrated cyclohexane) $)^{2}$ as reference compound. The concentration effect on fluorescence properties of compound AF was addressed by a Spex Fluorolog-2 F112AI spectrofluorimeter in front-face configuration.

Singlet oxygen in air-equilibrated solution ( $\approx 1 \times 10^{-5} \mathrm{M}$ ) was produced by sensitization experiments from the three fluorene derivatives in CH and Tol . The ${ }^{1} \mathrm{O}_{2}$ phosphorescence spectra was detected through a spectrofluorimeter FS 5 (Edinburgh Instrument) equipped with a InGaAs detector. Phenalenone ( $\Phi_{\Delta}=0.95$ in CH and 0.99 in Tol) was used as reference compound for comparison purpose. ${ }^{3}$ The same spectrofluorimeter was employed to acquire the phosphorescence spectra of compound $\mathbf{F}$ in the glass matrix constituted by methyl-cyclohexane and 3 -methyl-pentane ( $\mathrm{MC}-3 \mathrm{MP}$ ), $9 / 1 \mathrm{v} / \mathrm{v}$ ratio, at 77 K by exciting the sample at the maximum absorption wavelength with a microsecond pulsed lamp with tunable excitation frequency (from 40 Hz to 0.25 Hz ).

Triplet properties were measured by laser flash photolysis (Edinburgh LP980) with a pump pulse centered at 355 nm (third harmonic of a Continuum Surelite II Nd:YAG laser, Spectra Physics) with nanosecond time-resolution (pulse width 7 ns and laser energy $<1 \mathrm{~mJ}$ puls ${ }^{-1}$ ) coupled with a PMT for signal detection. A pulsed xenon lamp was then used to probe the absorption properties of the produced excited states. Energy transfer experiments in de-aerated conditions have been exploited in order to acquire the sensitized triplet transient absorption spectra and in particular to experimentally determine the triplet energy, employing a wide selection of sensitizers of known triplet energy, acting both as donors and acceptors, and deriving the quenching kinetic constants. The detailed procedure can be found in the relative paragraph (Section 3.3.1). Triplet-triplet absorption coefficients ( $\varepsilon_{T}$ ) were taken from ref. ${ }^{1}$ and measured in the case of the newly-synthetized compound by energy transfer experiments (see below Section 3.3.2) from $\mathbf{F}$ to the all-trans- $\alpha$, $\omega$-di(2-thienyl)octatetraene (D2TO, $\Phi_{\mathrm{T}}<0.005$ and $\varepsilon_{\mathrm{T}}=53000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at 465 nm$)^{4}$ in CH . An actinometry approach, deepened in Section 3.3.3, was then used to measure the triplet quantum yields considering Thioxanten-9one (TX) in $\mathrm{MeCN}\left(\Phi_{\mathrm{T}}=0.66^{5}\right.$ and $\varepsilon_{\mathrm{T}}=30000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at $630 \mathrm{~nm}^{6}$ and anthracene $(\mathbf{A})$ in $\mathrm{CH}\left(\Phi_{\mathrm{T}}=0.71\right.$ and $\varepsilon_{\mathrm{T}}=45500$ $\mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at 422 nm$)^{7}$ as references with known $\Phi_{\mathrm{T}}$ and $\varepsilon_{\mathrm{T}}$ values. The uncertainties were estimated to be about $\pm 15 \%$ on $\Phi_{\mathrm{T}}$ and $\pm 10 \%$ in the product $\Phi_{T} \times \varepsilon_{T}$. All measurements were performed by purging the sample with pure nitrogen. The study of the concentration effect on $\Phi_{T}$ was intrinsically limited by the experimental technique. Therefore, a narrow range of concentrations (corresponding to absorbances: $\mathrm{A}_{355} \approx 0.1,0.3,0.5$ up to $\mathrm{A}_{355}=1$, condition of total absorbance) was analyzed (see dedicated Section 3.3.4).

The experimental setup for the femtosecond transient absorption and fluorescence up-conversion measurements have been widely described elsewhere ${ }^{8-11}$. Particularly, the $800-\mathrm{nm}$ radiation is amplified by the Ti:Sapphire laser system (Spectra Physics) and, successively, converted into the 266 and 400-nm excitation pulses (ca. 60 fs) by Apollo (2 $2^{\text {nd }}$ and $3^{\text {rd }}$ Harmonic generator). A small portion of the fundamental laser beam ( 800 nm light) enters the transient absorption spectrometer (Helios, Ultrafast Systems), passes through an optical delay line (time window of 3200 ps ) and is finally focused onto a Sapphire crystal ( 2 mm thick) to generate a white-light continuum (450-800 nm), used as probe. The temporal resolution is about 150 fs and the spectral resolution 1.5 nm . In the Up-Conversion set up (Halcyone, Ultrafast System), the $400-\mathrm{nm}$ pulse excites the sample whereas the fundamental laser beam acts as the "gate" light, after passing through a delay line, which is then summed to the sample emission promoting the up-conversion process. The time resolution is about 200 fs while the spectra resolution is 1.5 nm . Most measurements were carried out under the magic angle condition in a $2-\mathrm{mm}$ cell considering $0.5<\mathrm{A}<1$ at $\lambda_{\text {pump }}\left(\mathrm{ca} .1 \times 10^{-4} \mathrm{M}\right.$ ). We have employed a 400 nm pump for NF and $\mathbf{A F}$, as this wavelength is at the red-edge of their absorption spectra; a 266 nm pump was used for $\mathbf{F}$ as this sample shows negligible absorption at 400 nm . The solution was stirred during the experiments to avoid photoproduct interferences. Photodegradation was checked recording the absorption spectra before and after the time-resolved measurement, where no significant change was observed. The experimental 3D data matrixes were firstly analyzed performing the Global Analysis by Surface Xplorer PRO (Ultrafast Systems) software, and successively through GloTarAn software in order to obtain the Evolution-Associated Spectra (EAS) considering a consecutive kinetic model. The SF mechanism was then detailed by running the Target Analysis with the same software, considering consecutive and parallel steps to describe the evolution of transients providing the Species Associated Spectra (SAS). ${ }^{12,13}$.

Quantum mechanical calculations. Energy level diagram, including the first electronic excited singlet and triplet states, was predicted by quantum mechanical calculations using the Gaussian 16 package ${ }^{14}$. CAM-B3LYP have been chosen as method to perform both $\mathrm{S}_{0}, \mathrm{~S}_{1}$ and $\mathrm{T}_{1}$ geometry optimization and to draw the theoretical absorption spectra by employing DFT and TD-DFT levels of theory for these small organic push-pull systems. ${ }^{15}$ Every calculation was submitted setting $6-31 \mathrm{~g}+\mathrm{G}(\mathrm{d}, \mathrm{p})$ as basis set including the solvent effect (cyclohexane) according to the conductor-like polarizable continuum model (CPCM) ${ }^{16}$. Vertical, $\mathbf{E}\left(\mathbf{S}_{1}\right)_{\mathrm{FC}}=\mathrm{E}\left(\mathbf{S}_{1}, \mathbf{S}_{0}\right)-\left(\mathbf{E}\left(\mathbf{S}_{0}, \mathbf{S}_{0}\right)\right.$ and $\mathbf{E}\left(\mathbf{T}_{1}\right)_{\mathrm{FC}}=\mathbf{E}\left(\mathbf{T}_{1}, \mathbf{S}_{0}\right)-\left(\mathbf{E}\left(\mathbf{S}_{0}, \mathbf{S}_{0}\right)\right.$, and adiabatic, $\mathbf{E}\left(\mathbf{S}_{1}\right)_{\mathrm{REL}}$ $=E\left(\mathbf{S}_{1}, \mathbf{S}_{1}\right)-\left(E\left(\mathbf{S}_{0}, \mathbf{S}_{0}\right)\right.$ and $E\left(\mathbf{T}_{1}\right)_{\text {REL }}=E\left(\mathbf{T}_{1}, \mathbf{T}_{1}\right)-\left(E\left(\mathbf{S}_{0}, \mathbf{S}_{0}\right)\right.$, energy gaps have been considered when verifying the feasibility of

SF according to the principal energy criterion $\left(E\left(\mathrm{~S}_{1}\right) \geq 2 \mathrm{~T}_{1}\right)$ and establishing the thermodynamic of the process: $\Delta \mathrm{E}_{\mathrm{s}-\mathrm{TT}}=$ $2 E\left(T_{1, ~ R E L}\right)-E\left(S_{1, ~ F C}\right)$.

## 2. Synthesis and characterization of $F$

2,7-bis[3,4-bis(dodeciloxy)-phenylethynyl] fluorene: Dry toluene ( 6 ml ), dibromofluorene ( 1.1 mmol ), Cul ( 0.02 mmol ), $\operatorname{Pd}(\mathrm{PPh} 3) 4(0.02 \mathrm{mmol})$ and diisopropylamine ( 3 ml ) were placed in a reactor and degassed under inert atmosphere at $0^{\circ} \mathrm{C}$. Dodecyloxy-4-ethynylbenzene ( 2 mmol ) was then added and the mixture was kept at $75^{\circ} \mathrm{C}(20 \mathrm{~h})$. Next, the solvent was fully evaporated, and the crude reaction mixture was purified by column chromatography (silica gel, petroleum ether/dichloromethane 4:1). Yield: 62\%.
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta: 7.80-7.56(\mathrm{~m}, 6 \mathrm{H}), 6.91-6.86(\mathrm{~m}, 4 \mathrm{H}), 6.62(\mathrm{~m}, 2 \mathrm{H}), 3.95(\mathrm{~m}, 10 \mathrm{H}), 1.75(\mathrm{~m}, 8 \mathrm{H}), 1.38-1.21(\mathrm{~m}, 72 \mathrm{H})$, 0.89 (m, 12H).

## 3. Photophysical properties

Figure S1. Concentration effect on absorption spectra of AF in Tol.

Figure S2. Concentration effect on fluorescence spectra of AF in Tol at different excitation wavelengths ( $\lambda_{\text {exc }}=365,384$, 400 nm , respectively from the left panel to the right panel).

### 3.2 Phosphorescence measurements

### 3.2.1 Singlet oxygen phosphorescence

Figure S3. Comparison between phosphorescence spectra of singlet oxygen produced by NF (red) and phenalenone (gray) in toluene solution (ca. $1 \times 10^{-5} \mathrm{M}$ ) for comparison. The spectra are recorded in the same experimental conditions including slits width and absorbance value (ca. 0.6) at the excitation wavelength, being the maximum absorption wavelength.

### 3.2.2 Phosphorescence spectrum of compound $F$

Figure S4. Phosphorescence spectrum of compound $\mathbf{F}$ in MC-3MP matrix (pink line) obtained by exciting the sample ( 3 $\times 10^{-5} \mathrm{M}$ ) at 350 nm by 10 Hz pulsed lamp at 77 K . The phosphorescence excitation spectrum (black line) and the absorption spectrum in CH at room temperature (dashed line) are also shown.

### 3.3 Nanosecond transient absorption measurements

Figure S5. Transient absorption spectra of $\mathbf{F}$ (left) and $\mathbf{A F}$ (right) in de-aerated CH (ca. $1 \times 10^{-5} \mathrm{M}$ ) obtained by ns flash photolysis experiments ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) and theoretical triplet absorption spectra (violet bars) obtained by quantum mechanical calculations.

Figure S6: Triplet transient absorption spectra of compound $\mathbf{F}$ (ca. $1 \times 10^{5} \mathrm{M}$ ) in solvents of different polarity obtained by ns flash photolysis experiments ( $\lambda_{\mathrm{exc}}=355 \mathrm{~nm}$ ) in de-aerated conditions.

### 3.3.1 Determination of the triplet energy by sensitization

The determination of the triplet energy via sensitization was achieved by energy transfer experiments from many energy donors (Acetophenone, Acph, thioxanthene-9-one, TX, 2,2-bisthienylketone, DTK, 2'-Acetonaphtone, 2-AcNph, Chrysene, Cry, 1'-Acetonaphtone, 1-AcNaph, 1-Napthaldehyde, 1-Naph, 2,3-Butanedione, Byl, and 7H-Benz(a)anthracen-7-one, 7BAone) in DCM and several acceptors (Pyrene, Pyr, 7Baone, 2,4-Pentandione Iron(III) derivative, 2,4PDI, Anthracene, A, and D2TO) in CH. ${ }^{2,4,17-19}$ When using the fluorene molecules as acceptors, the solvent was conveniently chosen considering the reduced triplet quantum yield of the fluorene derivatives in a polar environment such as DCM, thus limiting the direct excitation of the acceptor, and to avoid the hydrogen abstraction affecting DMF solutions. Acetonitrile was also excluded due to solubility issues. The experimental procedure starts from recording the kinetics corresponding to the triplet absorption maxima ( $\lambda_{T}$ ) of the solution containing the donor alone $\left(A_{D} \approx 0.9\right.$ at 355 nm ), in order to obtain its triplet lifetime $\left(\tau_{D}\right)$. Then, donor/acceptor mixtures ( $A_{\text {TOT }}=A_{D}+A_{Q} \approx 1.1$ ) have been analyzed by recording the kinetics in correspondence of the donor and acceptor maximum wavelengths and fitted, accounting for the shorter lifetime of the quenched donor ( $\tau_{D+A}$ ) or the rise-decay dynamics at the $\lambda_{\top}$ of the acceptor, being the body of proof of the accomplished energy transfer. The transient absorption spectra of the donor/acceptor mixtures were also acquired. To avoid any inaccuracy, in the cases where the ESA signals of the energy donor were found to be substantially overlapped to those of the acceptor, the rise time at the $\lambda_{T}$ of the acceptor has rather been considered. Triplet lifetimes of the donor ( $\tau_{\mathrm{D}}$ ) and quenched donor $\left(\tau_{\mathrm{D}+\mathrm{A}}\right)$, together with the concentration of the acceptor ([Q]) have been manipulated in the well-known Stern-Volmer equation (Eq. 1) for the calculation of the quenching constants ( $k_{q}$ ):
$\frac{\tau_{D}}{\tau_{D+A}}=1+k_{q} \cdot[Q]$

The energy transfer experiments from DTK in DCM ( $\lambda_{T}=630$ and 400 nm ) to the fluorene derivatives and from fluorenes $\left(\lambda_{T}=490,530 \mathrm{~nm}\right)$ to Pyr in CH ( $\lambda_{T}=422 \mathrm{~nm}$ ) are shown in detail as representative examples (Figures S7-S9).

Figure S7: Transient triplet absorption spectrum (left) and representative kinetics (right) of DTK in DCM obtained by ns flash photolysis $\left(\lambda_{\text {exc }}=355 \mathrm{~nm}\right)$ in de-aerated conditions.

Figure S8: Kinetics (left panels) and transient absorption spectra (right panels) of DTK/F, DTK/AF and DTK/NF mixtures in DCM obtained by ns flash photolysis ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) in de-aerated conditions.

Figure S9: Kinetics recorded at $\lambda_{T}$ of fluorene derivatives in CH obtained by ns flash photolysis ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) in deaerated conditions.

Figure S10: Representative kinetics (left panels) and transient absorption spectra (right panels) of $\mathbf{F} / \mathbf{P y r}, \mathbf{A F} / \mathbf{P y r}$ and NF/Pyr mixtures in CH obtained by ns flash photolysis $\left(\lambda_{\mathrm{exc}}=355 \mathrm{~nm}\right)$ in de-aerated conditions.

Generally, in all cases the quenching constant values, obtained through Eq.1, are in line with the diffusional constants in the investigated solvents at $20^{\circ} \mathrm{C}^{2}$ when considering sensitizers with $\mathrm{E}_{\mathrm{T}} \geq 2.44 \mathrm{eV}(1-\mathrm{NphA})$ in DCM $\left(\mathrm{k}_{\mathrm{q}} \sim 3 \times 10^{10} \mathrm{M}^{-1}\right.$ $\left.\mathrm{s}^{-1}\right)$. In addition, the fluorene derivatives act as efficient sensitizers, with a diffusional rate ( $\mathrm{k}_{\mathrm{q}} \sim 3 \times 10^{9} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ ), when the $\mathrm{E}_{\mathrm{T}} \leq 1.85 \mathrm{eV}$, namely when using $\mathbf{A}$ as acceptor in CH solutions. As a consequence, the unknown triplet energies of our samples are comprised between 2.44 and 1.85 eV , pointing out that Pyrene ( 2.12 eV ) and $7 \mathrm{H}-\mathrm{Benz}(\mathrm{a})$ anthracen-7-one $(2.04 \mathrm{eV})$ represent the crucial experiments and for this reason are reported in detail for all the investigated fluorene compounds in Table S4.

Table S3: Comparison between quenching constants $\left(\mathrm{k}_{\mathrm{q}}, \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$ of fluorene derivatives.

|  | 1-Naph <br> (Donor) | Pyr <br> (Acceptor) | $7 B A o n e$ <br> (Acceptor) | A <br> (Acceptor) |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{E}_{\mathrm{T}} / \mathrm{eV}$ | 2.44 | 2.12 | 2.04 | 1.85 |
| $\mathbf{F}$ | $5.18 \mathrm{E}+09$ | $9.94 \mathrm{E}+07$ | $9.90 \mathrm{E}+08$ | $2.65 \mathrm{E}+09$ |
| AF | $2.93 \mathrm{E}+09$ | $5.48 \mathrm{E}+06$ | $1.68 \mathrm{E}+09$ | $1.65 \mathrm{E}+09$ |
| $\mathbf{N F}$ | $1.29 \mathrm{E}+09$ | $2.61 \mathrm{E}+07$ | $1.74 \mathrm{E}+09$ | $4.47 \mathrm{E}+09$ |

Based on these data, we can derive the following conclusions about the triplet energies as obtained from the experiments:

- Surprisingly, the $k_{q}$ values found for Fluorenes to Pyr perfectly reproduce the $\mathrm{E}_{\mathrm{T}}$ trend as obtained by TD-DFT calculations: $\mathbf{F}>\mathbf{N F}>\mathbf{A F}$, as evidenced by the lowest quenching constant for $\mathbf{A F} / \mathbf{P y r}$ in CH . A more activated, and then slower, energy transfer process occurs due to the lower triplet energy of $\mathbf{A F}\left(5.5 \times 10^{6} \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$ if compared to $\mathbf{N F}\left(2.6 \times 10^{7} \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$ and $\mathbf{F}\left(1.0 \times 10^{8} \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$. As for $\mathbf{A F}, \mathrm{E}_{\mathrm{T}}<2.12 \mathrm{eV}$.
- $\quad$ : considering the phosphorescence spectrum peaked at $560 \mathrm{~nm}(2.21 \mathrm{eV})$ in MC-3MP and the low quenching constant of about $1 \times 10^{8} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ in the case of $\mathrm{F} / \mathrm{Pyr}$ in CH , the triplet energy reasonably lies between 2.21 and 2.12 eV .
- $\quad \mathbf{N F}$ : the analogous values of $k_{q}$ when considering 7BAone/NF in DCM ( $\left.1.3 \times 10^{9} \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$ and $\mathbf{N F} / 7 \mathrm{BAone}$ in CH $\left(1.7 \times 10^{9} \mathrm{M}^{-1} \mathrm{~s}^{-1}\right)$ suggest that $\mathrm{E}_{\mathrm{T}} \approx 2.04 \mathrm{eV}$.

### 3.3.2 Determination of the triplet absorption coefficient trough energy transfer experiments

The determination of the triplet absorption coefficient $\left(\varepsilon_{T}\right)$ is provided by energy transfer experiments from the donor (compound $\mathbf{F}$ ) to the energy acceptor (D2TO) applying the following equation:
$\varepsilon_{T}($ donor $)=\varepsilon_{T}$ (acceptor) $\cdot \frac{\Delta A_{M A X}(\text { donor })}{\Delta A_{M A X}(\text { acceptor })} \cdot f_{D} P_{T E} W$

Prior to dealing with Eq.3, it is important to define:

- $\quad \Delta A_{M A X}$ as the maximum value of the decay curve recorded at the maximum wavelength of the $\mathrm{T}_{0}-\mathrm{T}_{\mathrm{n}}$ spectrum $\left(\lambda_{T}\right)$;
- $\quad f_{D}$ as the fraction of absorbed light by the donor, defined by Eq. 3:
$f_{D}=\frac{A_{D}}{A_{T O T}}\left(\frac{1-10^{-A_{T O T}}}{1-10^{-A_{D}}}\right)$
where $A_{\text {TOT }}$ is the absorbance of the solution containing both the donor and the acceptor and $A_{D}$ the absorbance at 355 nm of the solution containing the donor alone (cuvette optical length 1 cm );
- $\quad P_{T E}$ as the energy transfer probability, given by:
$P_{T E}=\frac{k_{T D}^{\prime}-k_{T D}}{k_{T D}^{\prime}}$
Eq. 4
where ${ }^{k_{T D}^{\prime}}$ and $k_{T D}$ are the decay kinetic constants of the donor in the presence and in the absence of the acceptor, respectively;
- $\quad W$ as the correction factor accounting for triplet decay rate constants of the donor ( ${ }^{k^{\prime}}{ }^{2}$ ) and acceptor ( ${ }^{k_{T A}}$ ):
$W=\exp \left(-\frac{\ln \left(k^{\prime} / k_{T A}\right)}{\left({ }^{\left.k_{T D}^{\prime} / k_{T A}\right)-1}\right)}\right.$
Eq. 5
The experimental procedure required the acquisition of:

1. The triplet decay kinetics of the donor and the acceptor separately, at their relative maximum wavelengths (490 and 465 nm respectively);
2. The decay kinetic of the solution containing the energy donor alone at the $\lambda_{T}$ of the acceptor ( 465 nm );
3. The kinetics of the mixture containing both the donor and the acceptor at the triplet maxima of the two species (490 and 465 nm )
in the same experimental conditions.

Figure S11: Kinetics obtained by ns transient absorption measurements ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) for the donor ( $\mathbf{F},{ }^{\prime} A_{D=0.9550, ~ c}$ $=1.93 \times 10^{-5} \mathrm{M}$ ), left, and the acceptor (D2TO) recorded at their relative $\lambda_{\mathrm{T}}$ in de-aerated conditions.

Figure S12: Kinetics obtained by ns transient absorption measurements ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) for the F/D2TO ( ${ }^{\text {TOT }}=$ 1.2596) mixture recorded at their relative $\lambda_{T}$ in de-aerated conditions.

According to the experimental results above and applying Eq.2:

$$
\begin{aligned}
& \varepsilon_{T}(\text { donor }) \\
& \\
& =\varepsilon_{T}(\text { acceptor }) \frac{\Delta A_{M A X}(\text { donor })}{\Delta A_{M A X}(\text { acceptor })} \cdot f_{D} \rho_{T E} W=53000 M^{-1} \mathrm{~cm}^{-1} \frac{0.0397}{0.0147} \cdot 0.806 \times 0.6 \\
& M^{-1} \mathrm{~cm}^{-1}
\end{aligned}
$$

Table S4: Molar absorption coefficients of first triplet excited state $\left(\varepsilon_{T}\right)$ of compounds $\mathbf{F}, \mathbf{A F}$ and $\mathbf{N F}$ in $\mathbf{C H}$.

|  | $\mathbf{F}$ | $\mathbf{A F}$ | $\mathbf{N F}$ |
| :---: | :---: | :---: | :---: |
| $\lambda_{\mathrm{T}} / \mathrm{nm}$ | 500 | 530 | 530 |
| $\varepsilon_{\mathrm{T}} / \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ | 35500 | $28000^{*}$ | $31000^{*}$ |

*from ref. ${ }^{1}$

### 3.3.3 Determination of the triplet quantum yields

Analogously to AF and NF in ref. ${ }^{1}$, the triplet quantum yields ( $\Phi_{T}$ ) of compound $\mathbf{F}$ in different solvents were measured by quantitative experiments with two reference compounds using an actinometry approach: thioxhanten-9-one, $\mathbf{T X}$, in $\operatorname{MeCN}\left(\Phi_{\mathrm{T}}=0.66 \text { and } \varepsilon_{\mathrm{T}}=30000 \mathrm{M}^{-1} \mathrm{~cm}^{-1} \text { at } 630 \mathrm{~nm}\right)^{5,6}$ and anthracene, $\mathbf{A}$, in $\mathrm{CH}\left(\Phi_{\mathrm{T}}=0.71\right.$ and $\varepsilon_{\mathrm{T}}=45500 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at $422 \mathrm{~nm})^{7}$. Eq. 6, stated below, has then been applied to determine the triplet quantum yield:
$\frac{\Delta A_{M A X}(\text { sample }) / A_{\text {sample }}}{\Delta A_{M A X}(\text { reference }) / A_{\text {reference }}}=\frac{\phi_{T} \cdot \varepsilon_{T}(\text { sample })}{\phi_{T} \cdot \varepsilon_{T}(\text { reference })}$

In practise, the kinetics of compound $\mathbf{F}$ in different solvents ( $\lambda_{T}=490$ in CH and 500 nm in Tol, EtAc and DMF) and TX in $\operatorname{MeCN}\left(\lambda_{T}=630 \mathrm{~nm}\right)$ and A in $\mathrm{CH}\left(\lambda_{T}=422 \mathrm{~nm}\right)$ at the $\lambda_{T}$ of the maximum triplet absorption were recorded in the same experimental conditions of laser power, time and flux rate of pure Nitrogen purged for the de-aeration process. We carefully tuned the laser power and verified the mono-exponential fitting of each acquired kinetic in order to avoid disturbing phenomena as triplet-triplet annihilation or second-order effects. In this manner, the $\triangle A_{M A X}$ has been estimated and manipulated in Eq.6. In addition, the triplet absorption coefficient was considered to be independent from solvent effect and thus kept constant when going from $\mathbf{C H}$ to DMF. The determination of $\Phi_{\mathrm{T}}$ of $\mathbf{F}$ in all solvents is shown as representative examples of the applied procedure. Taking advantage of two different references it was
possible to monitor the reliability of the results by mutually checking whether one standard could provide the literature $\Phi_{\mathrm{T}}$ value for the other one. For each reported measurement this relative error was $<15 \%$.

Figure S13: Kinetics obtained by ns transient absorption measurements ( $\lambda_{\text {exc }}=355 \mathrm{~nm}$ ) for the references (left) and compound $\mathbf{F}$ (right) at their $\lambda_{T}$ in de-aerated conditions.

Table S5: Experimental details for the determination of $\Phi_{\top}$ of compound $\mathbf{F}$ in solvents of different polarity ( $\lambda_{\text {exc }}=355$ $\mathrm{nm})$. The last two lines refer to the representative example of mutual check of the actinometry approach ( $\Phi_{\mathrm{T}}=0.66$ in the case of TX in MeCN and $\Phi_{\mathrm{T}}=0.71$ for A in CH ).

### 3.3.4 Concentration effect on the triplet quantum yields

The same experimental method was applied to measure the triplet quantum yields of the fluorene derivatives at different concentration levels. The study of the concentration effect is intrinsically limited by the experimental
technique. Therefore, a narrow range (from $A_{355} \approx 0.1$ up to $A_{355}=1$, condition of total absorbance) was analyzed, restraining the concentration interval between $2.5 \times 10^{-6}$ and $2.5 \times 10^{-5} \mathrm{M}$, considering the $\varepsilon_{G}$ shown in Table S8. Due to the lower absorption coefficient of $F$ in $C H$ it was possible to reach $\approx 9 \times 10^{-5} \mathrm{M}$ as upper concentration limit. The concentration effect on triplet yield of $\mathbf{F}$ in Tol is reported as representative example.

Table S7: Molar absorption coefficients at 355 nm for the ground state of investigated samples in CH and Tol.

| $\varepsilon_{\mathrm{G}} / \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at 355 nm |  |  |
| :---: | :---: | :---: |
