Supplementary Information

## S1 Exploration of Excited States

As mentioned in the main text there is a disagreement between time-dependent density functional theory (TD-DFT) and correlated wave function methods in the ordering of the excited states for small oligomers of $\operatorname{poly}\left(p\right.$-phenylene), $\mathrm{PP}_{n}$, where $n$ represents the oligomer length. The chemical structure of $\mathrm{PP}_{5}$ and the Cartesian coordinate system used is shown in Fig. S1, with even and odd oligomer lengths exhibiting $D_{2}$ and $C_{2 h}$ symmetry, respectively. Fukada and co-workers ${ }^{1}$ showed that when using the symmetry-adapted cluster configuration interaction method on $\mathrm{PP}_{2}$, in vacuo, the lowest adiabatic excitation is of $1^{1} \mathrm{~B}_{3}$ symmetry, disagreeing with TD-DFT calculations employing the PBE0 functional which instead have the optically bright $1^{1} \mathrm{~B}_{1}$ as the lowest energy transition. The gas-phase excited state landscape of $\mathrm{PP}_{2}$ to $\mathrm{PP}_{8}$ has also been investigated previously in Ref. 2 using both RI-CC2 and TD-B3LYP. This also showed a disagreement between the ordering of the vertically excited electronic states when using B3LYP and RI-CC2 which was especially apparent for $n=2,3$ and 4. For $n \geq 5$ the nature of the lowest vertical transition was in agreement between both methods.

Figure S1: Chemical structure of $\mathrm{PP}_{5}$ with specific numbering of non-equivalent carbon atoms and the Cartesian coordinate system used.

For each oligomer length of poly( $p$-phenylene) our TD-DFT calcuations predict that the lowest excited state, both in terms of the adiabatic and vertical excitation, is the optically bright state. The vertical transition is described by a single particle-hole transition from the highest occupied to lowest unoccupied molecular orbital, see Table S1 and Table S2 for the adiabatic (AEE) and vertical excited state energies (VEE) of $\mathrm{PP}_{n^{-}}-\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{PP}_{n^{-}}$ TEA, respectively. For SCS-ADC(2) the VEE of each symmetry is provided in Table S3 and Table S 4 for $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{PP}_{n}$-TEA, respectively. The excited state which matches
the ground state symmetry, A and $\mathrm{A}_{\mathrm{g}}$ for odd and even oligomer lengths, respectively, has been excluded as it is expected that this state will not be (one of) the lowest energy state(s). In terms of the VEE the picture is somewhat analogous to that in Ref. 2 in which they perform RI-CC2 calculation exclusively in vacuo. For $\mathrm{PP}_{2}$ the $1^{1} \mathrm{~B}_{2}$ and $1^{1} \mathrm{~B}_{3}$ states are quasi-degenerate, with the optically bright $1^{1} \mathrm{~B}_{1}$ state lying at almost 0.6 eV higher in energy. As we increase the oligomer length the bright state drastically lowers in energy when compared to $1^{1} \mathrm{~B}_{2} / 1^{1} \mathrm{~B}_{\mathrm{g}}$ and $1^{1} \mathrm{~B}_{3} / 1^{1} \mathrm{~B}_{\mathrm{u}}$ states. For $\mathrm{PP}_{4}$ the energy spanned by the three states is small at 0.06 eV . For $\mathrm{PP}_{5}$ and longer chain lengths the optically bright state is the lowest vertical excited state. We then turned out attention to the AEE of each symmetry for SCS-ADC(2). For $\mathrm{PP}_{2}-\mathrm{H}_{2} \mathrm{O}$ the lowest $\mathrm{SCS}-\mathrm{ADC}(2) \mathrm{AEE}$ is the $1^{1} \mathrm{~B}_{3}$ state $(4.588 \mathrm{eV})$ in agreement with Ref. 1 despite the inclusion of the implicit solvent environment. The higherlying $1^{1} \mathrm{~B}_{2}$ and $1^{1} \mathrm{~B}_{1}$ states are located at 4.709 and 4.818 eV , respectively. This disagrees with all DFT calculations which has this as the optically bright state. However, for $\mathrm{PP}_{3}$ and $\mathrm{PP}_{4}$ the lowest AEE for $\mathrm{ADC}(2)$ corresponds to the optically bright $1^{1} \mathrm{~A}_{u}$ and $1^{1} \mathrm{~B}_{1}$ state, respectively, now in agreement with the density functional theory equivalent calculations. Therefore, for $n \geq 5$ it was sufficient to only optimise the $1^{1} \mathrm{~A}_{u} / 1^{1} \mathrm{~B}_{1}$. The AEE for each symmetry for $n=2,3$ and 4 and for the bright state for $n \geq 5$ are provided in Table S3. Analogous findings were observed for for SCS-ADC(2) at the $\mathrm{PP}_{n}$-TEA, see Table S4.

Table S1: The VEE, and corresponding oscillator strength, and the AEE as a function of $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}$ for each of the exchange-correlation functionals considered. All energies correspond to electronic energies and are provided in terms of eV , with the oscillator strength having arbitrary units.

## S2 Generation of Absorption Spectra

The VEE and corresponding oscillator strengths obtained via TD-DFT and SCS-ADC(2) computations were then used to transform the stick peak spectra to an absorption spectrum, by simulating the effect of peak broadening. The absorption intensity (I) at each photon energy $\left(\mathrm{E}_{p}\right)$ is obtained as a sum of Gaussian functions, see Eq. 1, centred on the excitation energy of the specific state $\left(\mathrm{E}_{i}\right)$ and weighted by the corresponding oscillator strength $\left(f_{i}\right)$. A $\sigma$ value of 0.2 eV was used, corresponding to a full width at half maximum of 0.5 eV . The $\mathrm{E}_{p}$ ranged from 3.00 to 7.00 eV in 0.01 eV steps. The absorption spectra for each oligomer length employing various theoretical methods are provided in Fig. S2. To observe differences in the shape of the spectra, and not solely the height of the absorption peaks, each intensity is divided by the maximum intensity ( $\mathrm{I}_{\text {max. }}$.) across all intensities within the range of 3.00 to 7.00 eV , resulting in the normalised intensity (I'), see Eq. 2.

$$
\begin{gather*}
\mathrm{I}\left(\mathrm{E}_{p}\right)=\sum_{i}^{\text {Num. of States }} f_{i} e\left(\frac{-\mathrm{E}_{p}-\mathrm{E}_{i}}{2 \sigma}\right)^{2}  \tag{1}\\
\mathrm{I}^{\prime}\left(\mathrm{E}_{p}\right)=\frac{I\left(\mathrm{E}_{p}\right)}{\mathrm{I}_{\max }} \tag{2}
\end{gather*}
$$

Figure S2: The simulated absorption spectra as a function of $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}(\mathrm{A})$ and $\mathrm{PP}_{n}-\mathrm{TEA}$ (B) calculated using SCS-ADC(2), respectively. The simulated absorption spectra as a function of $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}(\mathrm{C})$ and $\mathrm{PP}_{n}-\mathrm{TEA}(\mathrm{D})$ calculated using TD-CAM-B3LYP, respectively. The simulated absorption spectra as a function of $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}(\mathrm{E})$ and $\mathrm{PP}_{n}$-TEA (F) calculated using TD-B3LYP, respectively. The simulated absorption spectra as a function of $\mathrm{PP}_{n}-\mathrm{H}_{2} \mathrm{O}$ (G) and $\mathrm{PP}_{n}$-TEA (H) calculated using TD-MN15, respectively.

## S3 Reaction Energetics

Table S5: Various free energy differences of interest within the proposed catalytic cycle, modeled within a water continuum model for each of the exchange correlation functionals. All energy differences are in terms of eV and when applicable pertain to the $\mathrm{C}_{3}$ hydrogen binding site.

Table S8: The free energy difference of competing reactions, for each of the exchangecorrelation functionals used in the presence of an $\mathrm{H}_{2} \mathrm{O}$ and TEA dielectric continuum.

| $\mathrm{H}_{2} \mathrm{O}$ |  |  |  |
| :---: | :---: | :---: | :---: |
| Reaction | B3LYP | CAM-B3LYP | MN15 |
| TEA $+\mathrm{TEA}^{\bullet+} \rightarrow$ TEA-H ${ }^{+}+\mathrm{TEAR}^{\bullet}$ | -0.02 | -0.07 | 0.07 |
| TEA $+\mathrm{TEAR}^{+}+\mathrm{H}_{2} \mathrm{O} \rightarrow$ TEA- ${ }^{+}+\mathrm{MeCHO}+$ DEA | -0.16 | -0.16 | 0.00 |
| TEA |  |  |  |
| Reaction | B3LYP | CAM-B3LYP | MN15 |
| TEA $+\mathrm{TEA}^{\bullet+} \rightarrow \mathrm{TEA}^{+} \mathrm{H}^{+}+\mathrm{TEAR}^{\bullet}$ | 0.00 | -0.05 | -0.04 |
| $\mathrm{TEA}+\mathrm{TEAR}^{+}+\mathrm{H}_{2} \mathrm{O} \rightarrow$ TEA-H ${ }^{+}+\mathrm{MeCHO}+$ DEA | -0.12 | -0.13 | 0.02 |

Figure S3: The predicted free energy profile for each step in $\mathrm{H}_{2} \mathrm{O}$ of sub-cycle I (A) and II (B). The predicted free energy profile for each step in TEA of sub-cycle I (C) and II (D). Data shown for $n=2$ (blue triangles), 4 (green squares), 6 (purple stars) and 7 (brown diamonds), calculated using CAM-B3LYP and provided relative to $\mathrm{PP}_{n}$ and TEA. The $x$-axis labels omit any reference to the SED or its degradation products.
