## Electrode preparation and electrochemical measurement

All electrochemical tests were conducted with a standard three-electrode system at the electrochemical workstation. A graphite rod and saturated calomel electrode (SCE) were used as the counter and reference electrode, respectively. All potentials were referenced to the reversible hydrogen electrode (RHE) by the equation  $E_{\text{RHE}} = E_{\text{(SCE)}} + 0.0591 \text{ pH} + 0.241$ . Typically, 2.5 mg of the catalyst powders was dispersed in 480  $\mu\text{L}$  of a 3:1 v/v water/ethanol mixed solvents along with 20  $\mu\text{L}$  of Nafion solution, and the mixture was sonicated for about 45 min to generate a homogeneous catalyst ink. Then, 5  $\mu\text{L}$  of the catalyst ink was drop-casting onto a polished glass carbon electrode, leading to a catalyst loading of 0.35 mg  $\text{cm}^{-2}$ . Polarization curves were acquired by sweeping the potential from 0 to -0.8 V (vs SCE) at a potential sweep rate of 5 mV/s. Accelerated stability tests were performed in 0.5 M  $\text{H}_2\text{SO}_4$  at room temperature by potential cycling between 0 to -0.8 V (vs SCE) at a potential sweep rate of 100 mV/s for a given number of cycles. The pH durability of catalyst was processed in different electrolyte media (0.5 M  $\text{H}_2\text{SO}_4$ , 1 M KOH). In all measurements, the SCE reference electrode was calibrated with respect to a reversible hydrogen electrode (RHE). The electrochemical impedance spectroscopy (EIS) was carried out in the range from  $10^5$  to 0.01 Hz. All the experiments were processed at room temperature. The OER activities were measured by linear sweep voltammetry (LSV) method with a scan rate of 5  $\text{mV s}^{-1}$  at room temperature in 1 M KOH solution. The stability measurements were tested by cyclic voltammetry scanning 1000 cycles (CV, sweep rate, 100  $\text{mV s}^{-1}$ ) and long-term chronoamperometry method. EIS was

carried out in the range from  $10^5$  to 0.01 Hz. The electrochemically surface area (ECSA) also was investigated by CV to determine the electrochemical double-layer capacitances ( $C_{dl}$ ). For overall-water splitting studies, the full electrolyze configuration was assembled using  $\text{Co}_2\text{P}@NPPC$  loaded on a carbon cloth as a two-electrode with the catalyst loading of  $1.25 \text{ mg cm}^{-2}$ .

### **DFT calculations**

The VASP program<sup>1-2</sup> was used for calculations. PBE functional<sup>3</sup> was employed, and the ENCUT parameter was set to 500 eV. The reciprocal space was sampled with Gamma point. Both lattice parameters and atom positions were fully optimized for each structure.<sup>4</sup> The Grimme's D3BJ correction<sup>5</sup> was employed to take account of dispersion interaction.
