## 1. Materials and General Methods

IND and ITIC derivatives were prepared by the method described below. Their chemical structures were fully confirmed by ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{19} \mathrm{~F}$-NMR, FT-IR, Mass spectroscopy, and elemental analysis. ${ }^{1} \mathrm{H}$-NMR and ${ }^{19} \mathrm{~F}-\mathrm{NMR}$ spectra were recorded on a Bruker Ascend 500 spectrometer and Avance III HD respectively. IR spectra were recorded on a Bruker TENSOR II (ATR). Mass spectra were acquired through the JEOL JMS-700 instrument. Elemental analyses were performed on Flash2000 (Thermo Fisher Scientific, Germany). UV-vis absorption spectra were recorded on a Shimadzu UV-3100 UV-VIS-NIR spectrometer. The DSC and TGA measurements were recorded using DSC 4000 (Perkin Elmer) and TGA 4000 (Perkin Elmer), respectively. Cyclic voltammetry data were measured on an AUTOLAB/PG-STAT12 model system by using $\mathrm{Bu}_{4} \mathrm{NPF}_{6}(0.1 \mathrm{M})$ in dichloromethane as electrolyte at a scan rate of $50 \mathrm{mV} / \mathrm{s}$. Potentials were referenced to the ferrocenium/ferrocene couple by using ferrocene as an internal standard. The photoemission spectroscopy was measured using a Hitachi High Tech (AC2). AFM measurement (tapping mode) was performed on a NX-10 (Park Systems). Density functional theory (DFT) calculations were carried out in the gas phase using Gaussian 09 quantum-chemical package. The geometry optimizations were performed using B3LYP functionals and $6-31 \mathrm{G}+(\mathrm{d}, \mathrm{p})$ basis set.

## SCLC measurement.

For space-charge-limited currents (SCLC) measurement, hole-only and electron-only devices were fabricated respectively with the configuration of ITO/PEDOT:PSS/BHJ layer/ $\mathrm{MoO}_{3}(10 \mathrm{~nm}) / \mathrm{Ag}(100 \mathrm{~nm})$ and ITO/ZnO/BHJ layer/PFN-Br/Al. The SCLC mobility was determined by using dark current under forward bias. The SCLC mobilities were calculated using the below equation:

$$
J=\frac{9}{8} \varepsilon_{r} \varepsilon_{0} \mu_{0} \frac{V^{2}}{L^{3}}
$$

where $J$ is the current density, $\varepsilon_{r}$ is the dielectric constant of the organic material (dielectric constant assumed to be 3 ), $\varepsilon_{0}$ is the permittivity of free space, $\mu_{0}$ is the zero-field hole mobility, $L$ is the polymer thickness, and the effective voltage, $V=V_{a p p l}-V_{b i}$, where $V_{a p p l}$ is the applied voltage to the device, and $V_{b i}$ is the built-in voltage. The SCLC mobility was calculated from the slope $\left(J \sim V^{2}\right)$.

## Photovoltaic Device Fabrication and Evaluation.

Indium tin oxide glass substrate with a sheet resistance of $15 \Omega \mathrm{sq}^{-1}$ were purchased from AMG tech (Korea). PBDB-T and PFN were purchased from Solarmer Materials Inc and 1-Materials, respectively. The patterned indium tin oxide (ITO) glass substrates $\left(1.5 \times 1.5 \mathrm{~cm}^{2}\right)$ were ultrasonicated for 20 min in the order of DI water, acetone, and isopropanol after cleaning with a detergent. Before spin coating, all of the glass/ ITO substrates were treated using UV-ozone equipment for 10 min . To form the hole transport layer, a PEDOT:PSS (Clavious P VP

AI 4083) was spin-coated at 5000 rpm for 30 s on ITO substrate, and then dried on a hot plate at $160{ }^{\circ} \mathrm{C}$ for 10 $\min$ in an ambient condition. For the deposition of photoactive layers, all of the substrate were moved to a glove box filled with nitrogen gas. For binary solution, PBDB-T and acceptor ( $1: 1 \mathrm{w} / \mathrm{w}$ ratio) in chlorobenzene: 1,8 DIO ( $99.5: 0.5 \mathrm{v} / \mathrm{v}$ ratio) were fully dissolved at $50^{\circ} \mathrm{C}$ for over 3 hours before use. For optimum ternary blend solutions, PBDB-T, ITIC, and acceptor 2 (1:0.95:0.05 w/w ratio) were fully dissolved at $50^{\circ} \mathrm{C}$ for over 3 hours before use. The total solution concentration of all blend solutions is $22 \mathrm{mg} / \mathrm{mL}$. The blend solution was spin-coated at 2200 rpm and dried at $120-130^{\circ} \mathrm{C}$ for 10 min . PFN ( 5 nm ) was spin-coated on photoactive layer. Finally, a 100 nm layer of Al was deposited by thermal evaporation under a vacuum of $10^{-6}$ Torr. The current density $(J)$-voltage $(V)$ characteristics of the solar cells were measured by using a Keithley 4200 source measurement unit. The solar cell performances were characterized under AM 1.5 G condition with an illumination intensity of $100 \mathrm{~mW} \mathrm{~cm}{ }^{-2}$, as generated using an Oriel Sol3A solar simulator (Oriel model 9023A). The measurements were performed using a mask with aperture area of $0.04 \mathrm{~cm}^{2}$ under an ambient atmosphere.

## 2. Synthesis

The compound 1 was purchased from Alfa Aesar, and the compound 2 and Benzo[b]thiophen-3(2H)-one 1,1dioxide (BTD) were purchased from Fluorochem. IDTT-CHO was purchased from Solarmer Materials Inc. All other chemicals were used as received.
