**Experimental section**

**Materials**

Methyl orange (MO), hydrogen peroxide, 3,3',5,5'-tetramethylbenzidine, o-phenylenediamine and Pyrrole (reagent grade, 98%) were purchased from Sigma-Aldrich, USA; Iron(iii) chloride (anhydrous, 98%) and horseradish peroxidase (300 units/mg) were provided by Thermo Fisher Scientific, USA; Potassium permanganate was supplied by Fisher Scientific, USA. All chemicals used without further purification.

**Fabrication of Mn-Fe-N-C SAC**

Firstly, 500 mg of methyl orange (MO) was dissolved in DI water, then 5 g of FeCl\textsubscript{3} was added under vigorous stirring to form an oxidized MO template. After stirring for 30 min, 1.5 mL
pyrrole was added to form the Fe$^{3+}$ doped polypyrrole nanotube (Fe-PPy NT). Secondly, the obtained Fe-PPy NT was dispersed in KMnO$_4$ solution at room temperature to prepare MnO$_x$ coated PPy nanotube. Last, Mn-Fe-N-C SAC was obtained from the pyrolytic process at 900°C under nitrogen atmosphere and ammonia for 30 min, respectively. Then using 0.5 M H$_2$SO$_4$ acid washing 4 h at 60°C.

**Catalyst characterization**

The materials were characterized using scanning electron microscopy (SEM, FEI Apreo VolumeScope) and transmission electron microscopy (TEM, Tecnai F20, 200 kV; Philips CM200 UT, 200 kV; JEOL ARM300F, 300 kV), X-ray photoelectron spectroscopy (XPS, ThermoFisher Thermo, Al Kα), and X-ray diffraction (XRD, Rigaku Miniflex 600, 40 kV). Nitrogen gas adsorptions were done using a Micromeritics ASAP 2020Plus at 77 K. Raman spectroscopy (Thermo Scientific DXR2xi) were measured with 455 nm excitation.

The X-ray absorption spectroscopy measurements at the Fe K-edge (7,112 eV) were performed at the Advanced Photon Source (APS) on the bending-magnet beamline 12-BM and 20-BM. A Fe metal foil was used to calibrate the X-ray beam energy and was simultaneously measured with each sample. The radiation was monochromatized by a Si (111) double-crystal monochromator. The harmonic rejection was accomplished with a Harmonic rejection mirror. All single-atom sample spectra were collected in fluorescence mode by vortex four-element silicon drift detector, and the standards (including the foil) have been measured in transmission mode. XAS data reduction and analysis were processed by Athena software. For wavelet transform analysis, the $\chi$(k) exported from Athena was input to the Hama Fortran code. The parameters were set as follows: k weight, 3; R range, 1-4 Å; k range, 0-10 Å$^{-1}$.

**Electrochemical measurements**

2.5 mg as-prepared catalysts were ultrasonically dispersed in a mixture that consists of 990 µL ethanol and 10 µL 1 wt% Nafion solution to form a concentration of 2.5 mg/ml catalyst ink. A certain volume of catalyst ink was coated onto the surface of the working electrode with the loading of 0.6 mg/cm$^2$. Pt/C (20 wt%, Alfa Aesar) with a “standard” loading (0.1 mg/cm$^2$) was used as a benchmark. The electrochemical measurements were
performed using a standard three-electrode cell by CHI700E electrochemical workstation (CH Instruments). A graphite rod and calomel electrode (SCE) filled with saturated KCl aqueous solution were served as the counter electrode and reference electrode, respectively. All potential values refer to that of a reversible hydrogen electrode (RHE).

RDE and RRDE measurements were performed in O₂-saturated 0.1 M HClO₄. The scan rate was 5 mV/s. RRDE Polarization curves were collected at a disk rotation rate of 1600 rpm. The potential of the ring was set at 1.3 V in 0.1 M HClO₄. The collection efficiency of the RRDE (N) was 0.37. The peroxide yield (H₂O₂%) and the electron transfer number (n) were calculated as follows:

\[
H₂O₂\% = 200 \times \frac{I_r/N}{I_d + I_r/N}
\]

\[
n = 4 \times \frac{I_d}{I_d + I_r/N}
\]

where \(I_d\) is the disk current and \(I_r\) is the ring current.

The turn-over frequency (TOF) is estimated:

\[
TOF = \frac{j_k \times N_e}{W_Fe \times C_{cat} \times N_A/M_{Fe}}
\]

Where \(j_k\) is the kinetic current density (mA cm⁻²) at 0.8 V, \(N_e\) is electron number per Coulomb 6.24×10¹⁸, \(W_Fe\) is the metal content in the catalyst, \(C_{cat}\) is the catalyst loading on the electrode, \(N_A\) is Avogadro constant 6.022×10²³, \(M_{Fe}\) is the molar mass of Fe 55.85 g · mol⁻¹.

All LSV tests were measured at a rotating speed range from 1000 to 2200 rpm at the scan rate of 10 mV/s. Koutecky-Levich (K-L) plots to present the linear relation between \(j⁻¹\) and \(ω⁻¹/²\) were obtained based on the following equations:

\[
j⁻¹ = j_L⁻¹ + j_K⁻¹ = B⁻¹ω⁻¹/² + j_K⁻¹
\]

\[
B = 0.62nFCE_Dō²/3 \nu^{1/6}
\]

\[
j_k = j^*j_L/(j_L-j)
\]

where \(j\) means the measured current density, \(j_L\) is the diffusion-limiting current density, \(j_K\) corresponded to the kinetic current density, \(ω\) is the rotation rate (rpm), and \(n\) is the number
of electron transfers. $B^{\perp}$ means the slope of K-L plots, $F$ is the Faraday constant (96485 C/mol), $C_0$ is the bulk concentration of O$_2$ (1.2 $\times$ 10$^{-3}$ mol/L in 0.1 M HClO$_4$), $D_0$ is the diffusion coefficient of O$_2$ (1.93$\times$10$^{-5}$ cm$^2$/S in 0.1 M HClO$_4$), and $\nu$ is the kinematic viscosity of the electrolyte (0.01 cm$^2$/S in 0.1 M HClO$_4$).

**Colorimetric experiment**

The 3,3’,5,5’-tetramethylbenzidine (TMB) and o-phenylenediamine (OPD) were used as substrates for the colorimetric reaction of prepared samples. Specifically, same concentration Mn-Fe-N-C SAC and Fe-N-C SAC were dissolved, respectively. TMB and OPD were dissolved in DMSO to 10 mg mL$^{-1}$ and then 100 mL of the solution were added to the above solutions, respectively. The obtained mixtures were incubated in dark at 37°C for 5 min. All absorption spectra were performed by Tecan Safire2 Multi-Mode Microplate Reader.

**Figure S5** STEM dark-filed image and elemental maps of Fe-N-C SAC.
Figure S6 High-resolution N 1s spectra of Mn-Fe-N-C SAC and Fe-N-C SAC, respectively. The spectrum of N 1s could be fitted into four peaks around ~398 eV, ~400 eV, ~401 eV and ~402 eV, which correspond to pyridinic N, pyrrolic N, graphitic N and oxidized N, respectively.[3, 4]

Figure S7 Corresponding EDS linear scan profiles of Fe and Mn in Mn-Fe-N-C SAC.
Figure S8 High-resolution Fe 2p spectra of (a) Mn-Fe-N-C SAC and (b) Fe-N-C SAC, respectively. For Fe 2p, four peaks around ~709 eV, ~713 eV, ~718.9 eV, ~720 eV and ~727 eV were assigned to Fe$^{2+}$ 2p$_{3/2}$, Fe$^{3+}$ 2p$_{3/2}$, Fe$^{2+}$ 2p$_{1/2}$ and Fe$^{3+}$ 2p$_{1/2}$ on the basis of binding energies, respectively.[5-7]
Figure S9. Corresponding EXAFS fitting curve of Mn-Fe-N-C SAC in k space.

Table S1. Structural parameters of samples obtained by fitting the EXAFS data. Parameters include average coordination number (N), path distance (R), R-space range for fitting (R-Range: 1-3), Debye-Waller factor ($\sigma^2$), and the R-Factor of the fitting. An amplitude reduction factor ($S_0^2$) of 0.794 was obtained by fitting the Fe foil.
