Reagents

**Ferritin production by bacteria**

The ferritin heavy chain (FTH, UniProtKB accession; P02794) was produced by a previously method with some modifications.[Ref 1] *Escherichia coli* BL21(DE3) was transformed with an FTH expression plasmid, pET-FTH, and was cultivated in LB medium (Luria-Bertani, Becton, Dickinson and Company, Sparks, MD, USA) with 100 µg/mL ampicillin at 37 °C for 24 h. Harvested bacteria were disrupted by an ultrasonic wave (140 W for 5 min) and centrifuged at 5,000 × g for 5 min. The supernatant was then boiled at 60 °C for 20 min. After removing the debris by centrifugation at 8,000 × g for 15 min and 0.22 µm filtration, a clear supernatant was loaded into an anion-exchanger column (HiPrep Q HP 16/10, Cytiva, Marlborough, MA, U.S.A.). FTH was eluted with an NaCl gradient (0 to 0.7 M) in 50 mM Tris-HCl buffer (pH 8.0) at a flow rate of 3.0 mL min⁻¹. After concentration of the eluate containing FTH by ultrafiltration (Vivaspin 20-100K, MWCO 100 kDa, Cytiva), FTH was purified using a gel filtration column (HiPrep 26/60 Sephacryl S-300 HR, Cytiva) equilibrated with 10 mM Tris-HCl (pH 8.0) at a flow rate of 1.3 mL min⁻¹. The FTH yield was 50 mg L⁻¹ of broth.

**Characterization of ferritin**

Protein concentration and purity. The concentration and purity of ferritin were measured by reverse phase chromatography using PLRP-S 300A (3 µm, 150 mm × 4.6 mm, Agilent Technologies, Santa Clara, CA, USA). Samples were applied to the reverse phase column at a flow rate of 1.0 mL min⁻¹ with a linear elution gradient from 24% to 56% acetonitrile containing 0.1% trifluoroacetic acid (TFA) at 70 °C. The eluate was analyzed using a Chromaster HPLC system (Hitachi, Japan) and monitored at 220 nm absorbance. A recombinant human ferritin heavy chain protein (ab78877, Abcam, UK) was used as a standard.

Transmission electron microscopy (TEM) imaging. Nanostructures of ferritin-encapsulated oligonucleotides were analyzed using high-resolution TEM images (JEM-2200FS, JEOL, Japan). Ferritin solution (0.2 mg mL⁻¹; 2 µL) was dropped on a carbon-coated copper grid. After 1 min, the excess solution was wicked with filter paper and washed with 2 µL of water. The samples were stained with 1% phosphotungstic acid (PTA).

**Dynamic light scattering (DLS) and zeta potential analyses.**

For DLS analysis, a solution containing 0.5 mg mL⁻¹ ferritin was measured in 50 µL PBS (pH 7.4) at 25 °C using a Zetasizer Nano (Malvern Instruments, U.K.). The zeta potential of ferritin was also analyzed using a Zetasizer Nano. Phosphate buffer (50 mM, pH 7.0) containing 0.1 mg mL⁻¹ ferritin was measured in 750 µL of the buffer at 25 °C.
