## Electronic Supplementary Information

## Experimental Section

## Materials

Graphene oxide (GO) powder and activated carbon (AC) were supplied by Chengdu TIMESNANO. Nickel foam (NF, 1.7 mm ) was purchased from Taiyuan Lizhiyuan battery material Co., LTD., China. Cobalt nitrate hexahydrate $\left(\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right.$, 98.5\%), 2-methylimidazole (2-MIM, 99\%), thioacetamide (TAA, 99\%), sodium borohydride ( $\mathrm{NaBH}_{4}, 98 \%$ ), sodium hydroxide (99\%), ascorbic acid (98\%), methanol (99.9\%) and ethanol (99.9\%) were obtained from Aladdin Co., Ltd. All Chemicals and reagents were of analytical grade and used without further purification.

## Preparation of the rGO/NF

In a typical synthesis, 0.01 g GO powders were dispersed in 40 mL deionized water under stirring overnight followed by sonication for 1 h to form a homogeneous brown suspension. Then, 0.1 g ascorbic acid was added. After stirring for 30 min , a piece of clean NF was immersed into the suspension, and the suspension was heated at $80^{\circ} \mathrm{C}$ for 6 h in a water bath. Finally, the rGO/NF was taken out, cleaned with deionized water and ethanol, and dried at $60^{\circ} \mathrm{C}$ overnight.

## Preparation of the Co-ZIL-L nanosheet arrays on rGO/NF

1.313 g 2-MIM and 0.582 g Co $\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ were dissolved in 40 mL deionized water. Then, a piece of $\mathrm{rGO} / \mathrm{NF}$ was placed into the above solution, and the mixture was stirred for 10 min . After that, the solution was left static for 4 h at ambient
condition. Finally, the Co-ZIF-L/rGO/NF was cleaned with deionized water and ethanol, and dried at $60^{\circ} \mathrm{C}$ overnight.

## Preparation of the $\mathrm{Co}_{3} \mathbf{S}_{4} / \mathbf{r G O} / \mathrm{NF}$

The Co-ZIL-L/rGO/NF was immersed into an ethanol solution ( 40 mL ) of TAA $(0.120 \mathrm{~g})$ in a Teflon-lined autoclave. The autoclave was heated in a $120^{\circ} \mathrm{C}$ oven for 4 h. After cooling to room temperature, the $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ was taken out, washed and dried.

## Preparation of the $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$

$1.513 \mathrm{~g} \mathrm{NaBH}_{4}$ was dissolved in 80 mL deionized water. Then, the $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ was immersed into the solution for 2 h at ambient temperature. The product was washed with deionized water and ethanol for several times, and then dried overnight. The mass loading of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4}$ on $\mathrm{rGO} / \mathrm{NF}$ was around $2.4 \mathrm{mg} \mathrm{cm}^{-2}$.

## Characterization

The electrode materials were characterized by X-ray photoelectron spectrometer (XPS, Thermo Fisher Scientific ESCALAB 250Xi), X-ray diffractometer (XRD, Bruker AXS D8 Advance), electron paramagnetic resonance (EPR), field emission scanning electron microscope (FESEM, Hitachi S-4800) and transmission electron microscope (TEM, FEI Talos F200x) equipped with energy dispersive X-ray spectroscopy (EDS). $\mathrm{N}_{2}$ physisorption measurements were carried out at 77 K using a Micromeritics ASAP 2040 analyzer. The electrical conductivity was measured by 4probe conductivity measurements on ST-2722 semiconductor resistivity tester. UV-
visible absorption spectra were recorded by a spectrophotometer (PerkinElmer Lambda 35).

## Electrochemical measurements

The electrochemical properties of the $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ electrode were investigated by a cell with three-electrode configuration using Pt foil as counter electrode and saturated calomel electrode (SCE) as reference electrode in 2.0 M KOH aqueous solution. All the tests including galvanostatic charge-discharge (GCD), electrochemical impedance spectroscopy (EIS) and cyclic voltammetry (CV) were carried out on a CHI 660E electrochemical workstation (Shanghai Chenhua). The specific capacitance $\left(\mathrm{C}_{\mathrm{s}}, \mathrm{Fg}^{-1}\right)$ of the electrode material was calculated by following equation:

$$
C_{s}=\frac{I \times \Delta t}{m \times \Delta V}(\mathrm{~S} 1)
$$

where $I(\mathrm{~A}), \Delta t(\mathrm{~s}), \Delta V(\mathrm{~V})$ and $m(\mathrm{~g})$ were the discharging current, discharging time, potential window for the charge-discharge process and mass loading of active materials, respectively.

A two-electrode cell was assembled by using the $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ as positive electrode and an activated carbon (AC) as negative electrode in 2.0 M KOH . The mass loading of active materials on both electrodes was optimized to achieve charge (Q) balance, as described in following equation:

$$
\begin{equation*}
Q_{-}=m_{-} \times C_{-} \times \Delta V_{-}=m_{+} \times C_{+} \times \Delta V_{+}=Q_{+} \tag{S2}
\end{equation*}
$$

where $m(\mathrm{~g}), C\left(\mathrm{~F} \mathrm{~g}^{-1}\right)$ and $\Delta V(\mathrm{~V})$ represented the mass of active materials, specific capacitance, and charge-discharge potential window of both electrodes, respectively.

The energy density ( $\mathrm{E}, \mathrm{Wh} \mathrm{kg}^{-1}$ ) and power density ( $\mathrm{W} \mathrm{kg}{ }^{-1}$ ) of the $\mathrm{V}_{\mathrm{S}^{-}}$ $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / / \mathrm{AC}$ cell were calculated as follows:

$$
\begin{align*}
E & =\frac{C_{s} \times(\Delta V)^{2}}{2 \times 3.6}  \tag{S3}\\
P & =\frac{3600 \times E}{\Delta t} \tag{S4}
\end{align*}
$$

where $C_{s}\left(\mathrm{~F} \mathrm{~g}^{-1}\right), \Delta V(\mathrm{~V})$ and $\Delta t(\mathrm{~s})$ represented specific capacitance, working voltage window and discharging time of the $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / / \mathrm{AC}$ cell, respectively.

Fig. S1. (a) XRD pattern of ZIF-L/rGO/NF and FTIR spectrum of ZIF-L.

As shown in Fig. S1a, the XRD pattern of Co-ZIF is match well with that of simulated ZIF-L, indicating the successful synthesis of ZIF-L. The FTIR spectrum of ZIF-L scratched from the NF is shown in Fig. S1b. It shows main absorptions at $426 \mathrm{~cm}^{-1}$ (Co-N stretching), 688 and $753 \mathrm{~cm}^{-1}$ (out-of-plane bending of the imidazole ring), $993 \mathrm{~cm}^{-1}$ (C-N stretching), 1139 and $1302 \mathrm{~cm}^{-1}$ (C-H vibration), 1384 and $1419 \mathrm{~cm}^{-1}$ ( $\mathrm{C}-\mathrm{C}$ stretching), and $1567 \mathrm{~cm}^{-1}$ ( $\mathrm{C}=\mathrm{N}$ stretching), which is consistent with previous reports. ${ }^{1}$

Fig. S2. SEM images of rGO/NF.

Fig. S3. (a) Nitrogen physisorption isotherms and the corresponding pore size distributions of $\mathrm{Co}_{3} \mathrm{~S}_{4}$ and $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4}$.

The samples display the typical IV isotherm with H3 type hysteresis (Fig. S4a), implying that the sample contains mesopores. The specific surface area of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4}$ $\left(18.2 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)$ is larger than that of $\mathrm{Co}_{3} \mathrm{~S}_{4}\left(14.1 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)$. The pore size distribution (Fig. S4b) shows that there are two main mesopores at $\sim 2$ and 15 nm , respectively. Such hierarchical porous structure is conducive to the acquisition of electrolyte, and the large specific surface area will expose more electroactive sites, which is conducive to faradaic redox reactions.

Fig. S4. EDS patterns of the (a) $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and (b) $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

Fig. S5 XRD patterns of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.
X-ray diffraction (XRD) was used to determine the crystalline phases of $\mathrm{V}_{\mathrm{S}^{-}}$ $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$. In attempt to avoid the interference of NF , the samples were scratched from the substrate. As shown in Fig. S3, both samples display peaks at $31.4,38.0,50.2$ and $55.0^{\circ}$ corresponding to the (311), (400), (511), (440) planes of the cubic $\mathrm{Co}_{3} \mathrm{~S}_{4}$ (JCPDS No. 42-1448). Besides, the additional peak at $22^{\circ}$ is attributed to to S (JCPDS No. 24-1251) caused by decomposition of TAA.

Fig. S6 Raman spectra of $\mathrm{rGO} / \mathrm{NF}, \mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

Raman measurements were conducted to obtain more information on the structure of the sample. The Raman spectra of the samples are shown in Fig. S4. rGO/NF has two obvious peaks at 1345 and $1596 \mathrm{~cm}^{-1}$, corresponding to the D and G bands. The peak intensity ratio of the D and G bands $\left(I_{D} / I_{G}\right)$ can be used to measure the degree of disorder of carbon materials. During the removal of oxygen-containing functional groups of GO in the reduction process, the regular crystalline pattern in the graphene sheet ( $\mathrm{sp}^{2}$ carbon) is destroyed, resulting in an increment in the $\mathrm{I}_{\mathrm{D}} / \mathrm{I}_{\mathrm{G}}$ value. ${ }^{2}$ As shown in the Fig. S 5 , the $\mathrm{I}_{\mathrm{D}} / \mathrm{I}_{\mathrm{G}}$ value of $\mathrm{rGO} / \mathrm{NF}$ (1.32) is higher than that of thermally reduced GO $(\sim 0.91)$ and chemically reduced GO $(\sim 0.96),{ }^{3}$ indicating a higher degree of reduction. The apparent peak at $651 \mathrm{~cm}^{-1}$ is the characteristic band of cubic $\mathrm{Co}_{3} \mathrm{~S}_{4}$. The decrease of peak strength at $651 \mathrm{~cm}^{-1}$ of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ indicates that sulfur vacancies have been formed. Other active modes, such as $\mathrm{E}_{2 \mathrm{~g}}$ and $\mathrm{F}_{\mathrm{g}}$ are attributed to metal sulfur bonds which are found toward lower frequencies. ${ }^{4}$

Fig. S7 XPS survey spectra of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

Fig. $\mathbf{S 8}$ (a) CV curves, (b) plots of $\log (i) v s . \log (v)$, (c) the capacitance contributions of capacitive process and diffusion-controlled processes at 1 mV s -1 and (d) the relative contributions of capacitive process and diffusion-controlled process as a function of scan rates of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

The charge storage mechanism of the electrode can be analyzing the relationship between peak current $(i)$ and scan rate $(v)$ according to following equation:

$$
\begin{equation*}
i=\mathrm{a} v^{\mathrm{b}} \tag{S5}
\end{equation*}
$$

where a and b are constants. If b -value equals 0.5 , charge storage is diffusioncontrolled, while $\mathrm{b}=1$ manifests capacitive process. ${ }^{5}$ By the linear fitting $\log (i)$ vs $\log (v)$, the b -values are estimated to be 0.69 and 0.55 for anodic and cathodic process (Fig. S6b), indicating that the charge storage is mainly diffusion-controlled. Meanwhile, the current response can be divided into capacitive ( $\mathrm{k}_{1} v$ ) and diffusioncontrolled $\left(\mathrm{k}_{2} v^{1 / 2}\right)$ parts as follows:

$$
\begin{equation*}
i(\mathrm{~V})=\mathrm{k}_{1} v+\mathrm{k}_{2} v^{1 / 2} \tag{S6}
\end{equation*}
$$

where $\mathrm{k}_{1}$ and $\mathrm{k}_{2}$ are two constants. The fitting $\left(i(\mathrm{~V}) / v\right.$ vs. $\left.v^{1 / 2}\right)$ at a given potential $(\mathrm{V})$ determines the values of $\mathrm{k}_{1}$ and $\mathrm{k}_{2}$. The separation between capacitive and diffusioncontrolled processes at a scan rate of $1 \mathrm{mV} \mathrm{s}^{-1}$ is shown in Fig. S6c. As the scan rate rises from 1 to $5 \mathrm{mV} \mathrm{s}^{-1}$, the relative contribution fraction of diffusion-controlled process decreases from 83.5 to $49.5 \%$ (Fig. S6d), indicating that diffusion-controlled process governs the
charge
storage.

Fig. S9. Electrochemical properties of (a-c) NF and (d-f)rGO/NF. (a, d) CV curves, (b,
e) GCD curves and ( $c, f$ ) specific capacitances at various current densities.

The electrochemical properties of NF and rGO/NF are provided in Fig. S9. At the current density of $1 \mathrm{~mA} \mathrm{~cm}^{-2}$, the NF and $\mathrm{rGO} / \mathrm{NF}$ present very low capacitances of 9.5 and $110.5 \mathrm{mF} \mathrm{cm}^{-2}$, respectively. Thus, the contributions of NF and rGO are negligible

Fig. S10. (a) CV curves of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ at a scan rate of $5-50 \mathrm{mV} \mathrm{s}^{-1}$. (b) GCD curve of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ at a current density of $1-30$ A $\mathrm{g}^{-1}$.

Fig. S11. (a) Plots of $(\alpha h v)^{2} v s . h v$ and UV-vis adsorption spectra (inset), and (b) resistivity at five different points of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

The UV-vis diffuse reflectance spectra (Fig. S11a) are collected and the band gap energy $\left(\mathrm{E}_{\mathrm{g}}\right)$ is calculated as follows: ${ }^{6}$
$(\alpha h v)^{n}=\mathrm{K}\left(h v-E_{g}\right)$
where $h v$ is the photoenergy, $\alpha$ is the absorption coefficient, K is a constant relative to the material, and n is either 2 for a direct transition or $1 / 2$ for an indirect transition. The $\mathrm{Vs}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}\left(\mathrm{E}_{\mathrm{g}}=1.73 \mathrm{eV}\right)$ shows lower $\mathrm{E}_{\mathrm{g}}$ value than that of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}\left(\mathrm{E}_{\mathrm{g}}=1.84 \mathrm{eV}\right)$, implying the higher electronic conductivity of Vs$\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

4-probe conductivity measurements are also conducted, and the resistivity values at five different points are collected, as show in Fig. S11b. The average resistivity value of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}(0.33 \mathrm{~m} \Omega \mathrm{~cm})$ is lower than that of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}(0.41$ $\mathrm{m} \Omega . \mathrm{cm}$ ), further confirming the higher electronic conductivity of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$.

Fig. S12. (a) CV curves of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$. (b) CV curves of $\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$. (c)

The relationship between charging current density difference and scan rates.

The electrochemical active surface area (ECSA) of the electrode materials is evaluated by the double-layer capacitance $\left(\mathrm{C}_{\mathrm{d} 1}\right)$ method as follows: ${ }^{7}$
$\mathrm{ECSA}=\mathrm{C}_{\mathrm{d}} / \mathrm{C}_{\mathrm{s}}$
where $\mathrm{C}_{\mathrm{dl}}$ and $\mathrm{C}_{\mathrm{s}}$ refer to double layer capacitance and midpoint specific capacitance.
The $\mathrm{C}_{\mathrm{dl}}$ is measured in non-faradaic potential window (Fig. S12). As shown in Fig. 12 c , the $\mathrm{C}_{\mathrm{d} \text { l }}$ value of the $\mathrm{V}_{\mathrm{S}^{-}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ is $15.85 \mathrm{mF} \mathrm{cm}^{-2}$, which is much larger than that of $\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}\left(8.753 \mathrm{mF} \mathrm{cm}{ }^{-2}\right)$, revealing that the $\mathrm{NaBH}_{4}$ treatment can result in enriched electrochemical active sites, which is consistent with the $\mathrm{N}_{2}$ sorption results.

Fig. S13. (a) CV curves of AC at a scan rate of $5-100 \mathrm{mV} \mathrm{s}^{-1}$. (b) GCD curve of AC at a current density of $1-10 \mathrm{~A} \mathrm{~g}^{-1}$. (c) Specific capacitances of AC at different current densities.

Fig. S14. Photographs of the lighted red and green LEDs powered by two assembled
$\mathrm{V}_{\mathrm{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / / \mathrm{AC}$
ASCs.

Table S1 Comparison of $\mathrm{V}_{\mathbf{S}}-\mathrm{Co}_{3} \mathrm{~S}_{4} / \mathrm{rGO} / \mathrm{NF}$ and reported $\mathrm{Co}_{3} \mathrm{~S}_{4}$-based electrode materials.
