1. General Information

Unless otherwise declared, all the reagents were bought from commercial suppliers and used without additional purification. A glass tube (35 mL) with a rubber plug was used in hydroboration reactions unless otherwise noted. NHC-boranes reagent was prepared according to a previously reported procedure[1]. Thin layer chromatography (TLC) was performed on commercial silica gel plates and flash column chromatography was performed with 300-400 mesh silica gel cartridge. Visualization of TLC achieved using ultraviolet light (254 nm) or staining with Iodine. NMR spectra were recorded on a BRUKER AVANCE III 400 spectrometer (400 MHz for ^{1}H; 376 MHz for ^{19}F; 100 MHz for ^{13}C) instruments and are referenced relative to $CDCl_3$ (δ 7.26 ppm for ^{1}H, 77.16 ppm for ^{13}C) using TMS as internal standard. Resonances of hydrogen or carbon atoms bonded to the boron atom are weak (sometimes absent) in both ^{1}H or ^{13}C NMR spectra. Note: The protons on boron atom in the ^{1}H-NMR spectrum and the carbene carbon atom attached to the boron atom in the ^{13}C NMR spectrum are not detected owing to quadrupole broadening and spin–spin coupling with boron. Data are recorded as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q =quartet, m = multiplet, brs = broad singlet), coupling constant (*J*) in Hertz (Hz), and integration. High-resolution mass spectra (HRMS) were obtained on an Agilent mass spectrometer with electro spray ionization (ESI) as the ion source.

(6) Determination of Quantum yield

According to previous reported procedures,[4-6] the actinometry measurements were determined by standard ferrioxalate actinometry.

Preparation of potassium ferrioxalate solution (0.15 M): Potassium ferrioxalate trihydrate (0.737 g) and 95~98% H_2SO_4 (27 μL) were added to a 10 mL volumetric flask and filled to the mark with distilled water. The solution was stored in the dark.

Preparation of buffer solution: Dissolving 5.0 mg of phenanthroline and 1.13 g of sodium acetate in 5.0 mL of 0.5 M H_2SO_4 solution. The solution was stored in the dark.

The actinometry measurements: To determine the photon flux of the spectrophotometer, 2.0 mL of the ferrioxalate solution was placed in a cuvette and irradiated with 30W blue LEDs (λ ≈ 440 nm) for 90.0 seconds. After irradiation, 0.35 mL of buffer solution was added to the cuvette. The solution was then stored in the dark for 1 h to allow the ferrous ions to completely coordinate to the phenanthroline. In a similar method, a blank solution (a non-irradiated sample) was also prepared. The absorbance of irradiated and non-irradiated samples at λ = 510 nm was measured by UV-Vis spectrophotometry. Conversion was calculated using **Eq 1**,

$$mol\ of\ Fe^{2+} = \frac{V*\Delta A}{l*\varepsilon} = \frac{(0.00235\ L) * 2.532}{1\ cm*11100\ \frac{L}{mol}\ cm^{-1}} = 5.361*10^{-7}\ mol \qquad \textbf{(1)}$$

Where:

V = the total volume () of the solution after addition of phenanthroline;

ΔA = the difference in absorbance at 510 nm between the irradiated and non-irradiated solutions;

l = the path length (**l** = 1 cm);

ε = the molar absorptivity at 510 nm (**ε** = 11100 $L*mol^{-1}*cm^{-1}$).

Then, the photon flux can be calculated using **Eq 2**,

$$Photon\ flux = \frac{\text{mol of } Fe^{2+}}{\Phi * t * f} = \frac{\text{mol of } Fe^{2+}}{\Phi * t * (1-10^{-A})} = \frac{5.361*10^{-7}\ \text{mol}}{1.01*90\text{s}*0.999} = 5.904*10^{-9}\ \text{einstein/s} \quad \textbf{(2)}$$

Where:

Φ = the quantum yield for the ferrioxalate actinometer (**Φ** = 1.01 at λ = 436 nm);

t = irradiation time (**t** = 90 s);

A = the measured absorbance of the ferrioxalate actinometer solution at 440 nm (**A** = 3.000).

Reaction quantum yield: A dry glass tube equipped with a rubber plug and magnetic stir bar was charged with the ethyl cinnamate **1a** (0.20 mmol), NHC-BH_3 **2** (0.30 mmol), PhSSPh (4.4 mg, 10 mol%), and CH_3CN (2 mL). The tube was evacuated and backfilled with N_2 for three times, then was tied up nitrogen balloons. The reaction mixture was stirred at room temperature (around 30 °C) for 60 min under 30W blue LEDs irradiation (λ ≈ 440 nm). The solvent was removed in vacuo and the yield of product **3a** was determined by ^1H NMR based on 1,3,5-trimethoxybenzene as internal standard to be 17% (0.034 mmol). The quantum yield was determined using **Eq 3**,

$$\Phi = \frac{\text{mol of product}}{\text{flux} * t * f} = \frac{\text{mol of product}}{\text{flux} * t * (1-10^{-A})} = \frac{0.034*10^{-3}}{5.904*10^{-9}*3600*0.332} = 4.8 \quad \textbf{(3)}$$

Where:

A = the measured absorbance of the reaction solution at 440 nm (**A** = 0.175).

The quantum yield (Φ) of this photoreaction was determined to be 4.8, which suggesting the reaction is proceed in a radical-chain mechanism.
