15 **1) Supplementary Information for Computational Methods**

16 **Table S1.** Composition of the bulk aqueous solutions simulated in this work and
 17 corresponding densities and concentrations (molalities (b) in mol/kg, molarities in
 18 mol/L, mole fractions(x), density (d) in kg/L) at 300 K and 1 atm.

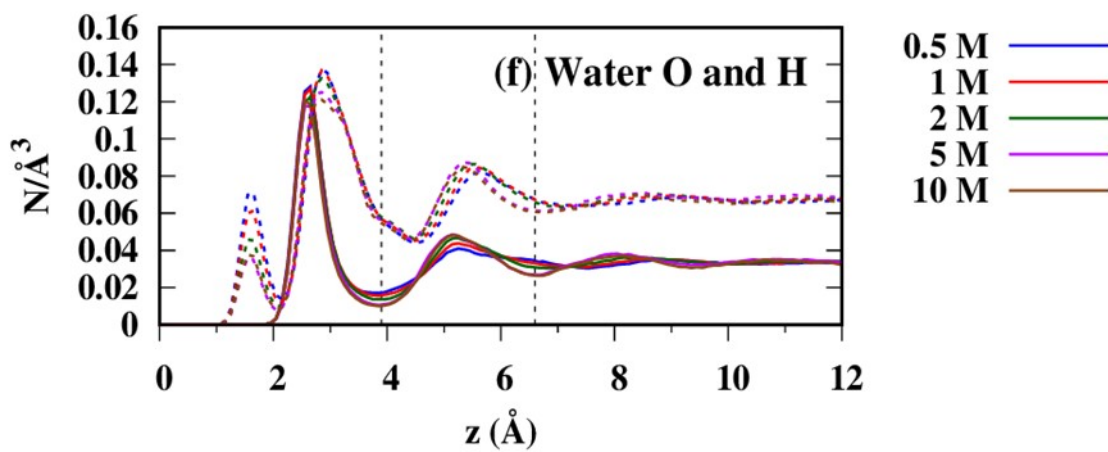

N(NaOH)	N(H ₂ O)	x(NaOH)	b _{NaOH}	d _{exp.}	d _{MD}	[NaOH] _{exp}	[NaOH] _{FF}
23	2520	0.0091	0.507	1.019	1.023	0.50	0.50
45	2510	0.0179	0.995	1.039	1.054	1.00	1.01
90	2490	0.0361	2.006	1.077	1.098	2.00	2.04
226	2470	0.0915	5.079	1.180	1.182	5.00	5.01
454	2330	0.1948	10.816	1.325	1.338	10.00	10.10

19

20

21 **2) Supplementary Information for Results and Discussion**

22 **Figure S1.** Number density profiles of water O (solid) and H (dashed). The vertical dashed
23 lines indicate the boundaries between the first water layer and the second water layer (3.9 Å),
24 and between the second water layer and the rest of the solution (6.6 Å)

25

26

27

28

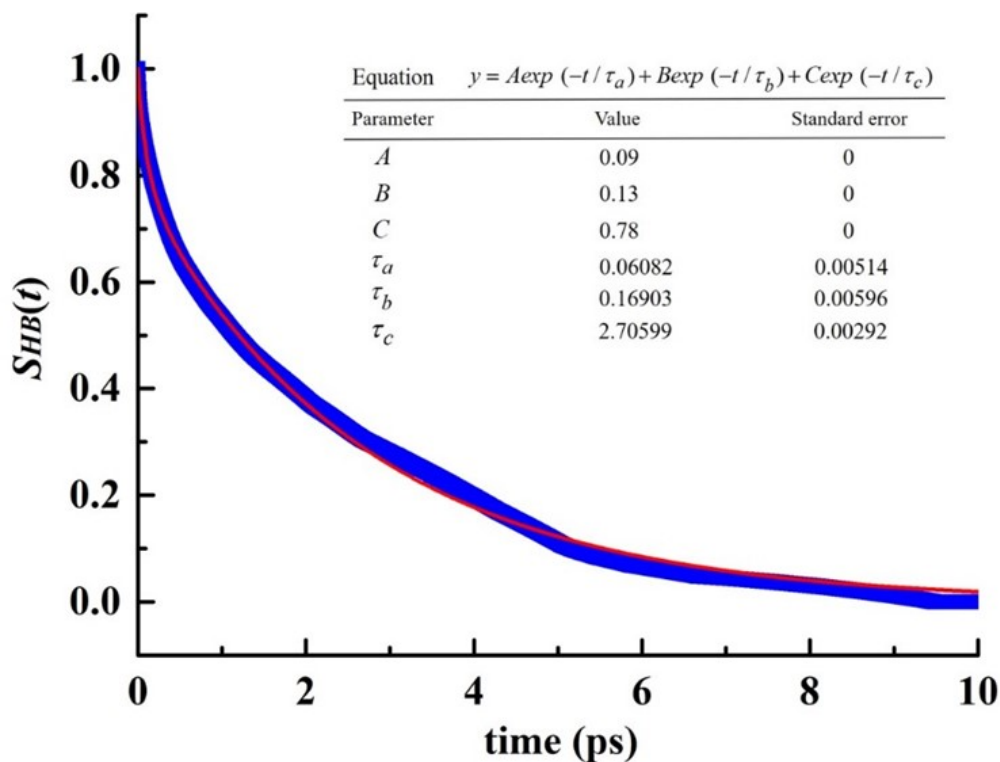

29

30 **Figure S2.** Density profile of one of the two outermost layers of the gibbsite slab. The
31 distribution of the z coordinate of the outermost O and H atoms are shaded.

32

33 As shown in Figure S2, we can clearly see that there are two orientations for the
34 surface hydroxyl groups. They are either roughly parallel to the surface (where the O
35 and H distributions overlap at $z \sim 20.4$ Å) or out of the plane formed by the surface ($z(\text{H})$
36 distribution centered at $z \sim 21.3$ Å). Integration of the first and second $z(\text{H})$ distributions
37 at and $z = 21.3$ Å indicates 58% of the hydroxyl groups are oriented out of the basal plane
38 i.e. point towards the solution (42% are parallel to the plane).

39

40 **Figure S3.** The comparison of the simulated $S_{HB}(t)$ of the OH⁻-surface HBs with the
 41 model obtained from a fit for the 0.5 M NaOH solution system

42 To determine the HB lifetimes (τ_s^{HB}), the $S_{HB}(t)$ curves have been fitted by three
 43 weighed exponentials (with a total weight of unity, *i.e.*, $A + B + C = 1$), which is
 44 expressed as

$$S_{HB}(t) = Aexp(-t/\tau_a) + Bexp(-t/\tau_b) + Cexp(-t/\tau_c)$$

45 where A , B , and C are tunable parameters, while τ_a , τ_b , and τ_c are the characteristic
 46 time constants. All the fitted parameters are listed in Table 2 and a typical fitting result
 47 is given in Figure S4. According to the fitted parameters, the HB lifetime τ_s^{HB} can be
 48 calculated as, $\tau_s^{HB} = A\tau_a + B\tau_b + C\tau_c$. All calculated τ_s^{HB} values are listed in Tables S2
 49 and S3.

50

51 **Table S2.** The fitting parameters and the average lifetime τ_s^{HB} of water-surface
 52 hydrogen bonds

$S_{HB}(t)$	A	B	C	τ_a	τ_b	τ_c	$\tau_s^{HB}(\text{ps})$
0.5 M	0.55	0.36	0.09	0.64	0.06	3.51	0.66
1 M	0.54	0.34	0.12	0.80	0.07	3.44	0.86
2 M	0.32	0.49	0.19	0.06	0.68	3.01	0.92
5 M	0.45	0.27	0.28	1.01	0.07	6.18	2.20
10 M	0.43	0.33	0.24	0.77	0.07	6.33	1.87

53

55 **Table S3** · The fitting parameters and the average lifetime τ_S^{HB} of OH⁻-surface

56 hydrogen bonds

$S_{HB}(t)$	A	B	C	τ_a	τ_b	τ_c	τ_S^{HB} (ps)
0.5 M	0.09	0.13	0.78	0.06	0.17	2.71	2.14
1 M	0.15	0.15	0.70	1.80	0.13	18.74	13.41
2 M	0.25	0.13	0.62	1.02	0.08	19.74	12.50
5 M	0.21	0.08	0.71	1.04	0.04	28.61	20.53
10 M	0.22	0.08	0.70	0.94	0.03	26.85	19.01

58

59 **Surface Charge Caused by Adsorption.** Figure S4a presents the interfacial

60 charge density distributions, which include the Na⁺, OH⁻ ions and the water molecules

61 on the gibbsite surface. We further calculated the interfacial electrostatic potential of

62 gibbsite/water due to NaOH adsorption. The electrostatic potential $\Psi(z)$ is related to

63 the interfacial charge density $\rho(z)$ via the Poisson equation⁵⁵:

$$64 \quad \frac{d^2\Psi(z)}{dz^2} = -\frac{\rho(z)}{\epsilon_0} \quad (1)$$

65 where $\epsilon_0 = 8.85 \times 10^{-12}$ C/m·V is the vacuum dielectric permittivity. Herein, the

66 electrostatic potential is computed by integrating Equation (3) twice. Figure 9b shows

67 the simulated $\Psi(z)$ near the gibbsite surface along the z axis. The positive charge

68 density for $z < 2.4$ Å corresponds to the Na⁺ of the IS layer and H_w, while the negative

69 charge density and electrostatic potential for 2.4 Å $< z < 3.3$ Å is due to the adsorbed

70 OH⁻ ions and O_w. With an increase in the NaOH concentrations, the interfacial charge

71 density below 3.2 Å becomes more asymmetric, with an increase in the negative charge

72 density for 2.4 Å $< z < 3.3$ Å compared to the relatively constant positive charge density

73 across the concentration range in the first area ($z < 2.4 \text{ \AA}$). This is due to the increase in

74 the ratio between the IS OH^- and the IS Na^+ (Figure 5).

75

76 **Figure S4.** (a) Interfacial charge density profiles due to the adsorption of NaOH and

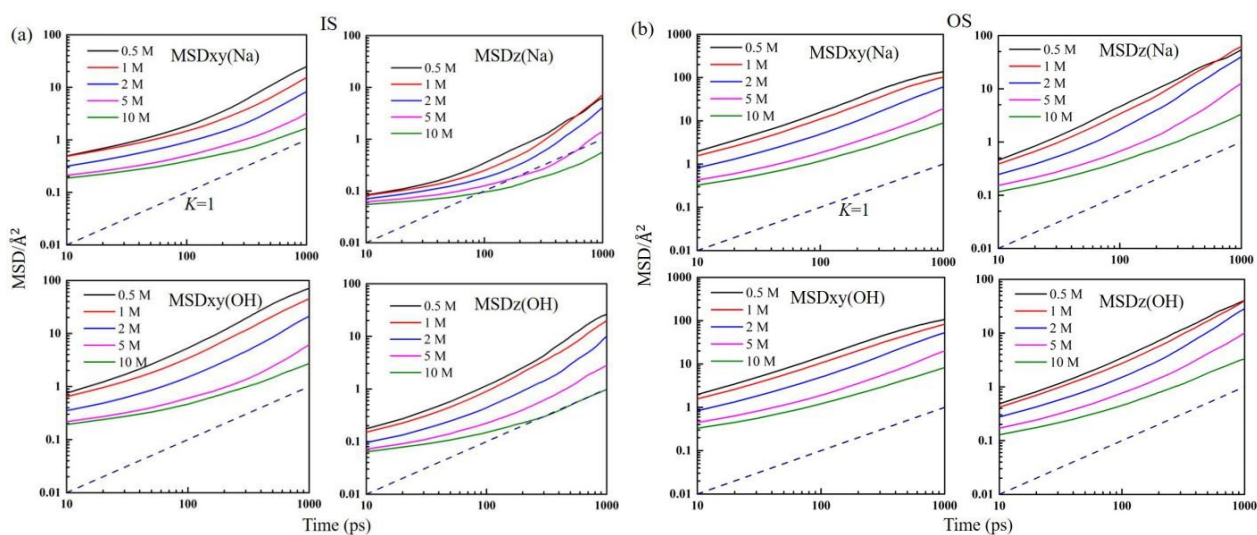

77 water as a function of distance from the gibbsite surface at different NaOH

78 concentrations. (b) Simulated electrostatic potential as a function of distance from the

79 gibbsite surface.

80

81

82 **Figure S5.** *MSDs* in log–log scale for ions in the interface region (IS(a) and OS(b)) in
83 all concentrations.

84

85

87 **Table S4.** The self-diffusion coefficients ($10^5 \cdot D_s/\text{cm}^2 \cdot \text{s}^{-1}$) of Na^+ and OH^- in IS

concentration	ion	IS-xy	IS-z	OS-xy	OS-z
0.5 M	Na	0.074	0.046	0.22	0.31
