## EXPERIMENTAL SECTION

### Materials

CoPor(CHO)<sub>4</sub> were synthesized following the published procedure.<sup>1</sup> All other reagents were commercially available and used as received.

### Characterization

NMR spectra were recorded on a Bruker DPX 400 spectrometer (<sup>1</sup>H: 400 MHz) in D<sub>2</sub>O. Powder X-ray diffraction (PXRD) was collected at room temperature on a PANalytical Empyrean series 3 diffractometer equipped with Cu K<sub>α</sub> radiation. FT-IR spectra were recorded as KBr pellets using a Bruker Tensor 37 spectrometer with 2 cm<sup>-1</sup> resolution. X-ray photoelectron spectroscopy (XPS) data were recorded on a Thermo Scientific K-Alpha system. Al K<sub>α</sub> X-ray (6 mA / 12 KV) was utilized as the irradiation source. All XPS measurements were performed in the CAE mode with the reference of C 1s (284.8 eV). The nitrogen adsorption and desorption isotherms were measured at 77 K and the CO<sub>2</sub> adsorption and desorption isotherms were measured at 298 K using a Micromeritics ASAP 2020 PLUS HD88 system. The samples were degassed at 90°C for 4 hours before the measurements. The thermogravimetric analysis (TGA) was performed on a Rigaku TG-DTA8122 instrument over the temperature range from 30 to 800°C under nitrogen atmosphere with a heating rate of 10°C/min. The metal contents of TPE-CoPor-COF and TPTPE-CoPor-COF were determined by inductively coupled plasma (ICP) analysis with an Agilent 5110 ICP-OES instrument.

Energy dispersive spectroscopy (EDS) mapping images were collected by transmission electron microscopy (JEM-2100F) at an operation voltage of 200 kV. Scanning electron microscopy (SEM) images were obtained on a HITACHI SU8010 microscope. UV-vis-NIR diffuse reflectance spectra (DRS) were recorded on a Shimadzu UV-2600 UV-vis-NIR spectrophotometer with BaSO<sub>4</sub> as the reference.

### **Synthesis of TPE-CoPor-COF**

CoPor(CHO)<sub>4</sub> (18.8 mg, 0.024 mmol), TPE(NH<sub>2</sub>)<sub>4</sub> (9.4 mg, 0.024 mmol), *n*-butanol (0.36 mL), *o*-dichlorobenzene (1.44 mL), and 6 M aqueous acetic acid (0.18 mL) were mixed in a Pyrex tube (9 × 6 mm, o.d. × i.d.). After sonication for 10 min, the Pyrex tube was rapidly frozen in a liquid nitrogen bath and degassed. After the above process was repeated three times, the tube was sealed with alcohol torch. After the Pyrex tube were warmed to room temperature, the tube was placed in an oven at 120°C for 72 h. The obtained COFs was placed in a Soxhlet extractor and washed with tetrahydrofuran (24 h) and chloroform (24 h) in turn. Finally, the product was dried under vacuum at 70°C for 12 h to provide TPE-CoPor-COF as purple powder (19.7 mg, ~70% yield).

### **Synthesis of TPTPE-CoPor-COF**

TPTPE-CoPor-COF (21.7 mg, ~61% yield) was synthesized following the similar procedure for TPE-CoPor-COF, except that TPE(NH<sub>2</sub>)<sub>4</sub> was replaced with TPTPE(NH<sub>2</sub>)<sub>4</sub>.

### **Electrochemical measurements.**

All electrocatalysis tests were conducted at room temperature in a standard three-electrode configuration using H-type cell on an electrochemical workstation (chi760E). In the H-type cell, two compartments equipped with 0.5 M KHCO<sub>3</sub> aqueous solution were separated by an anion exchange membrane (Nafion-117). Ag/AgCl electrode and Pt foil were served as the reference and counter electrodes, respectively. A catalyst-modified carbon fiber paper electrode was used as the work electrode.

COFs or CoPor(CHO)<sub>4</sub>/TPE(NH<sub>2</sub>)<sub>4</sub>/TPTPE(NH<sub>2</sub>)<sub>4</sub> (5 mg), Vulcan XC-72R carbon black (5 mg), ethanol (965  $\mu$ L) and Nafion perfluorinated resin solution (35  $\mu$ L, 10 wt. % in H<sub>2</sub>O) were mixed in a vial. Homogeneous pastes were formed after sonication for 60 min. To make sure that loading density of electrode materials was 1 mg cm<sup>-2</sup>, 100  $\mu$ L paste was dropped evenly onto a piece of carbon fiber paper (1 cm  $\times$  1 cm). The catalyst-modified carbon fiber paper electrode was placed in dark for 12 h. Before each electrochemical test, the electrolyte solution was saturated with Ar or CO<sub>2</sub> for 30 min. Linear sweep voltammetry (LSV) polarization curves were measured from 0 to -1.63 V vs. Ag/AgCl with a scan rate of 10 mV s<sup>-1</sup>. On account of the following equation:  $E$  (vs. RHE) =  $E$  (vs. Ag/AgCl) + 0.197 V + 0.059  $\times$  pH, the results of electrocatalysis in this work were presented vs. RHE. Besides, no  $iR$  compensation was carried out for all LSV polarization curves.

EIS spectroscopies were measured under an AC voltage of -1.5 V vs Ag/AgCl with 5 mV amplitude in a frequency range from 1000 kHz to 100 mHz. Cyclic voltammograms (CV) tests were conducted to obtain  $C_{dl}$  under the potential window from 0.29 to 0.19 V vs. RHE with various scan rates from 10 to 100 mV s<sup>-1</sup> to estimate

the ECSA.

### Structure modeling

The unit cells of the models were refined with the experimental PXRD data of TPE-CoPor-COF and TPTPE-CoPor-COF by using the Le Bail refinement. The cell parameters and the refined PXRD patterns were obtained until the values of  $R_{wp}$  and  $R_p$  converged.

### DFT calculation methods

Density functional theory (DFT) calculations were performed by PBE0-D3 method with Becke-Johnson damping.<sup>2,3</sup> A mixed basis set, including 6-31G(d) for C/H/N/O and SDD for Co, was utilized to optimize the structures and calculate the Gibbs free energies using Gaussian 09 program (version D.01).<sup>4-8</sup> Besides, the solvation model based on density (SMD) was used to simulate the aqueous environment.<sup>9</sup>

The electrocatalytic mechanisms were studied based on Nørskov's computational hydrogen electrode model.<sup>10,11</sup> In this technique, zero voltage was defined based on the potential energy ( $\mu$ ) of components involved in the reversible hydrogen electrode at all pH, T and p, therefore,  $\mu(\text{H}^+) + \mu(\text{e}^-) = \frac{1}{2}\mu(\text{H}_2)$  at a potential of 0 V. The pathways adopted for CO<sub>2</sub> reduction to CO in this work are listed below (\* represents the active site):

In addition, the pathway adopted for hydrogen evolution reaction (HER) in this work is shown as below:

### Calculation of Faradaic Efficiency

The Faradaic efficiencies (FEs) for CO production at each applied potential were calculated based on the following equation:

$$FE = \frac{j_{CO}}{j_{total}} = \frac{\nu_{CO} \times N \times F}{j_{total}}$$

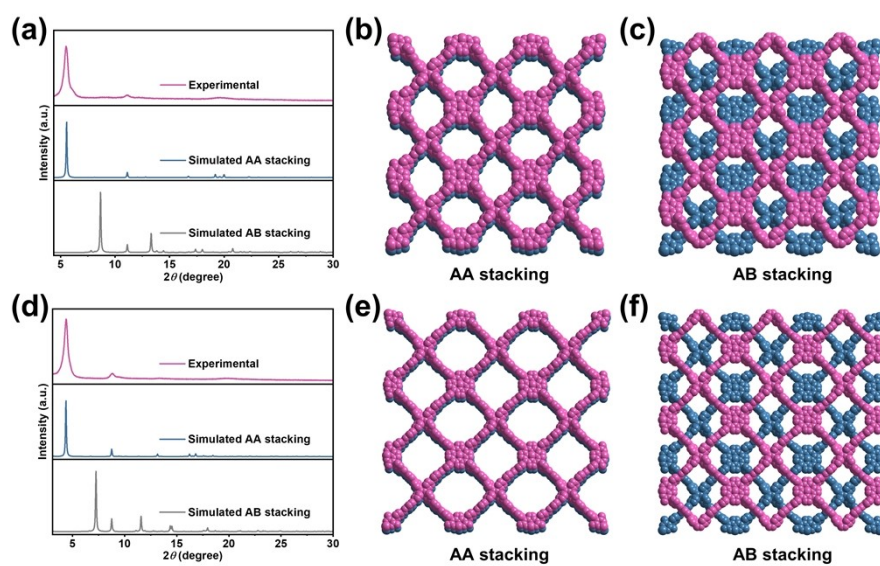

$j_{CO}$ : partial current density for CO production;  $j_{total}$ : total current density;  $\nu_{CO}$ : the production rate of CO; N: the number of transferred electrons (2 for CO); F: Faradaic constant, 96485 C mol<sup>-1</sup>.

### Calculation of Turnover Frequency (TOF, s<sup>-1</sup>)

The TOF for CO was calculated based on the following equation:

$$TOF = \frac{j_{total} \times FE_{CO} / NF}{\omega_{m_{cat}} / M}$$

$j_{total}$ : total current density;  $FE_{CO}$ : Faradaic efficiency for CO production (%); N: the number of electrons (2 for CO); F: Faradaic constant, 96485 C mol<sup>-1</sup>;  $\omega$ : the metal content of Co;  $m_{cat}$ : the catalyst mass in the electrode; M: the atomic mass of Co.
