**Figure S1.** N<sub>2</sub> adsorption-desorption isotherms of parent (Al-Beta), dealuminated (D-Beta) and Sn-substituted Beta zeolites (1, 2, 5Sn-Beta).

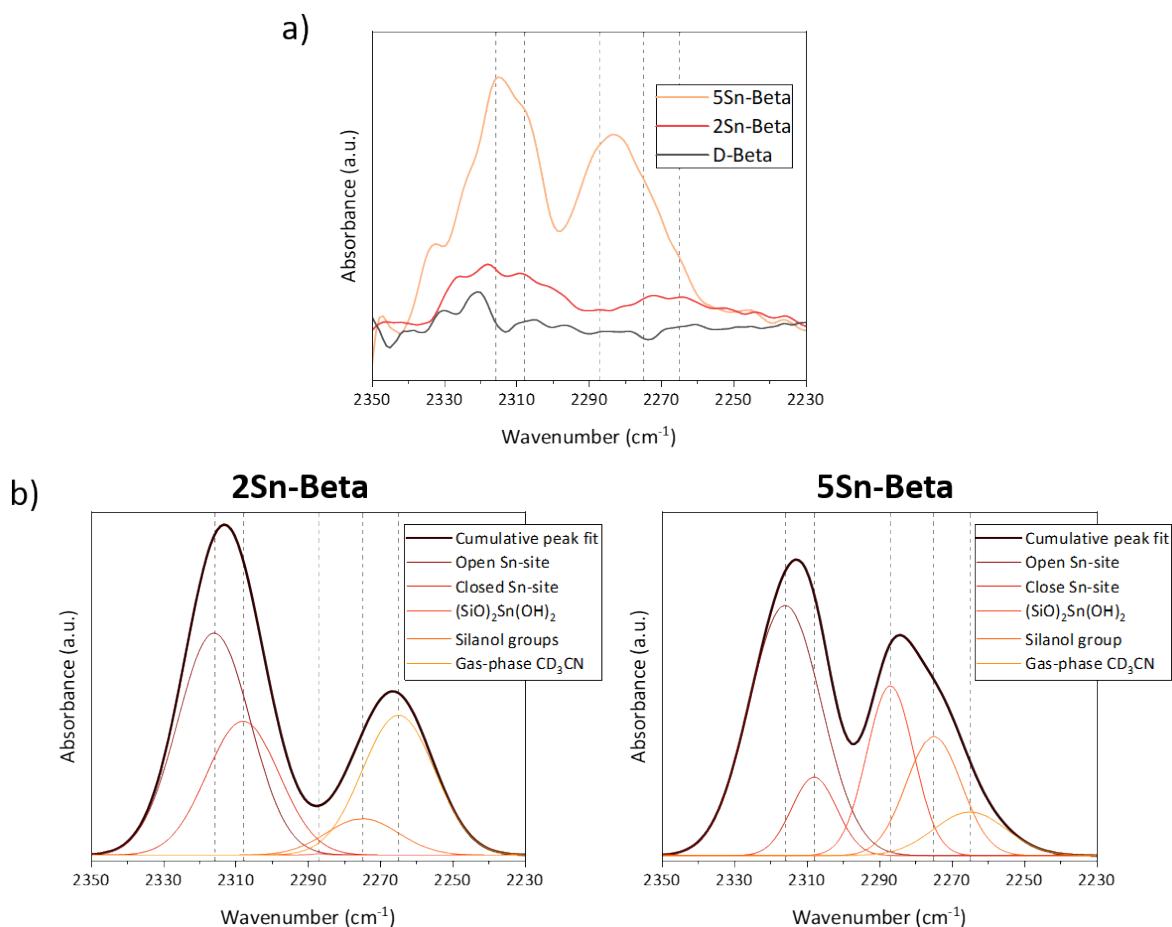

**Figure S2.** XRD diffraction patterns of parent, modified Beta zeolites and  $\text{SnO}_2$  zoomed in the region between 15 and 25 of  $2\theta$  to emphasise the contraction-expansion of the zeolite unit cell volume upon modification of its framework.

**Figure S3.** UV-Vis spectra of parent, dealuminated, and Sn-Beta zeolites as well as reference materials ( $\text{SnO}_2$ , D-Beta and impregnated  $5\text{SnO}_2/\text{D-Beta}$ ).

## Qualitative CD<sub>3</sub>CN-FTIR measurements

A DRIFTS cell (Praying Mantis™, Harrick) equipped with flat CaF<sub>2</sub> windows was loaded with 50 mg of sample in a sieve fraction of 100 – 200 µm. The sample was dehydrated at 673 K in flowing Ar (100 ml/min). Then, the Ar stream was saturated with CD<sub>3</sub>CN at 298 K and passed through the DRIFTS cell for 1 h, saturating the zeolite samples with CD<sub>3</sub>CN. Afterwards, gas-phase CD<sub>3</sub>CN was eliminated by heating the treated sample to 523 K for 30 min in Ar flow (100 ml/min). For the spectra, 128 scans with 4 cm<sup>-1</sup> resolution were taken in the range between 4000 – 800 cm<sup>-1</sup> at 298 K. Spectra of dehydrated samples were used as background for each respective CD<sub>3</sub>CN loaded sample. Deconvolution was performed in Origin applying Gauss fitting to peaks centered at 2316 cm<sup>-1</sup>, 2308 cm<sup>-1</sup>, 2287 cm<sup>-1</sup>, 2275 cm<sup>-1</sup> and 2265 cm<sup>-1</sup>, restraining full width half maximums between 5 to 20 cm<sup>-1</sup>.

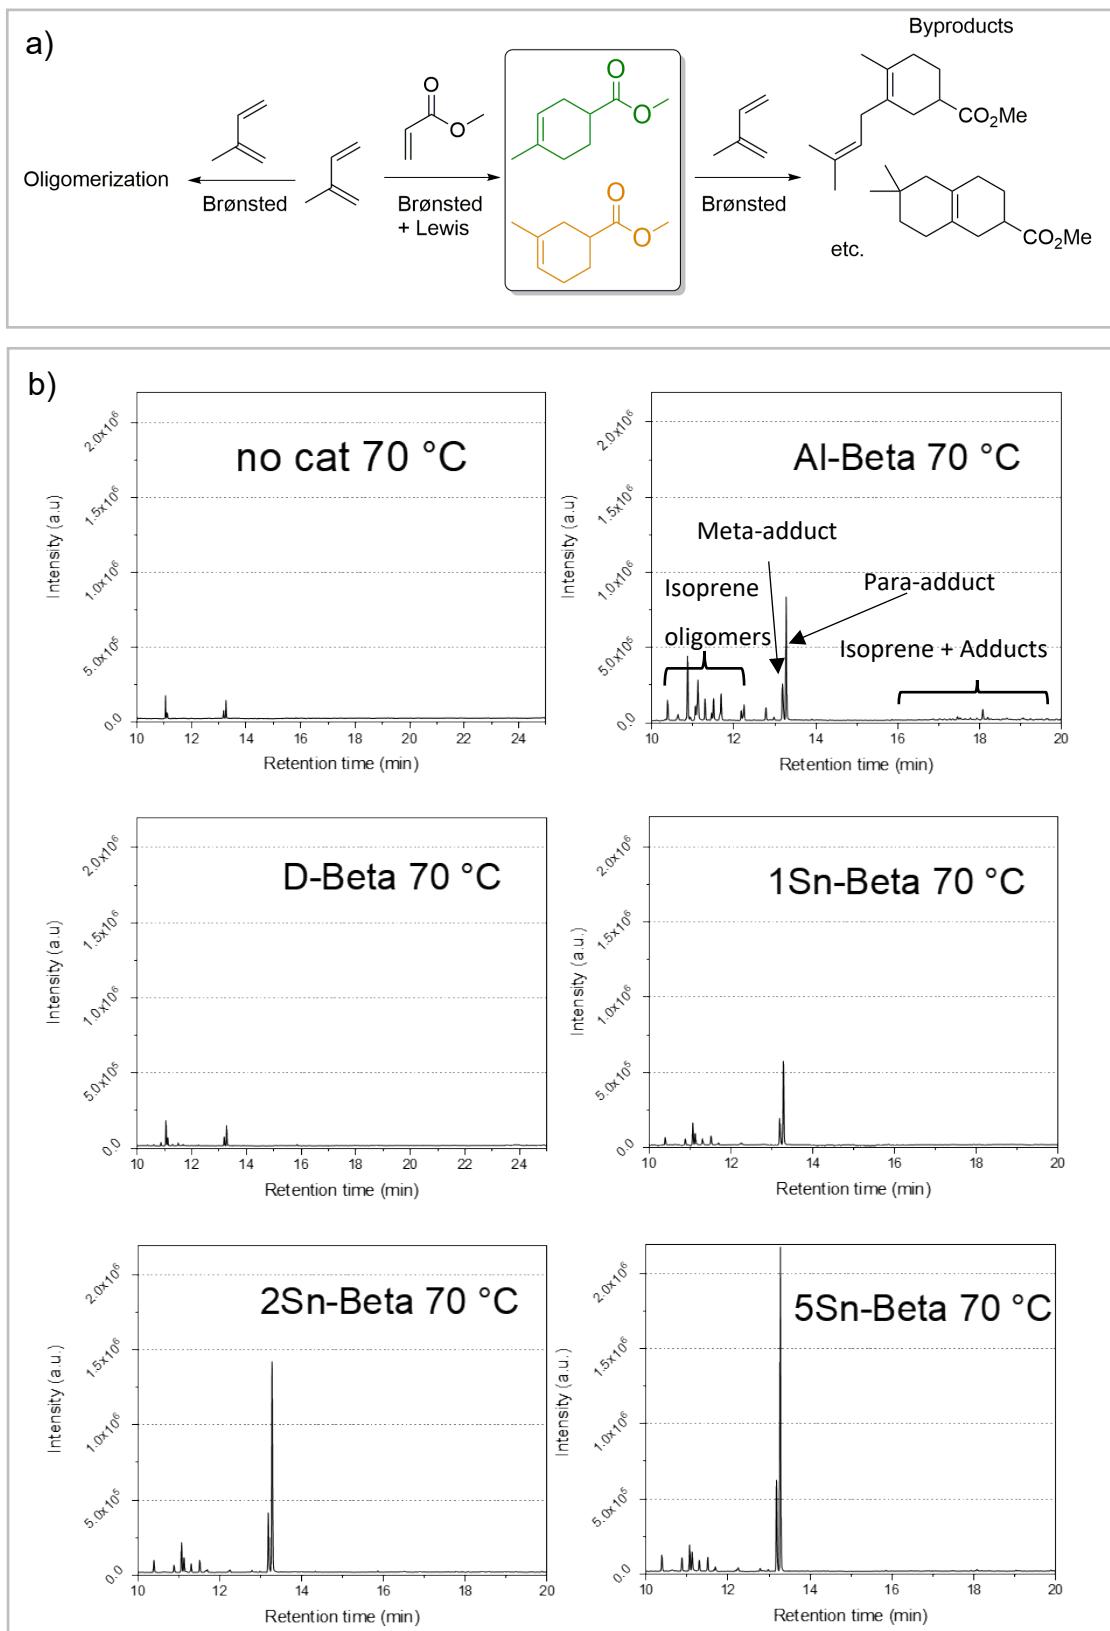

**Figure S4.** DRIFT spectra of CD<sub>3</sub>CN adsorbed samples. Reference lines refer to open Sn-sites (2316 cm<sup>-1</sup>), closed Sn-sites (2308 cm<sup>-1</sup>), (SiO)<sub>2</sub>Sn(OH)<sub>2</sub>-sites (2287 cm<sup>-1</sup>), silanol groups (2275 cm<sup>-1</sup>), and gas-phase CD<sub>3</sub>CN (2265 cm<sup>-1</sup>).<sup>1</sup> a) Comparison of spectra for D-Beta, 2Sn-Beta and 5Sn-Beta. b) Peak deconvolution of spectra for 2Sn-Beta (left) and 5Sn-Beta (right), including cumulative peak fit.

Figure S4 a) shows the adsorbed CD<sub>3</sub>CN DRIFT spectra on D-Beta, 2Sn-Beta and 5Sn-Beta. D-Beta does not show any significant absorption bands. For the Sn-Beta zeolites, 5Sn-Beta shows stronger absorption bands compared to 2Sn-Beta, probably due to higher density of Sn-sites. Both 2Sn-Beta and 5Sn-Beta show two absorption bands,

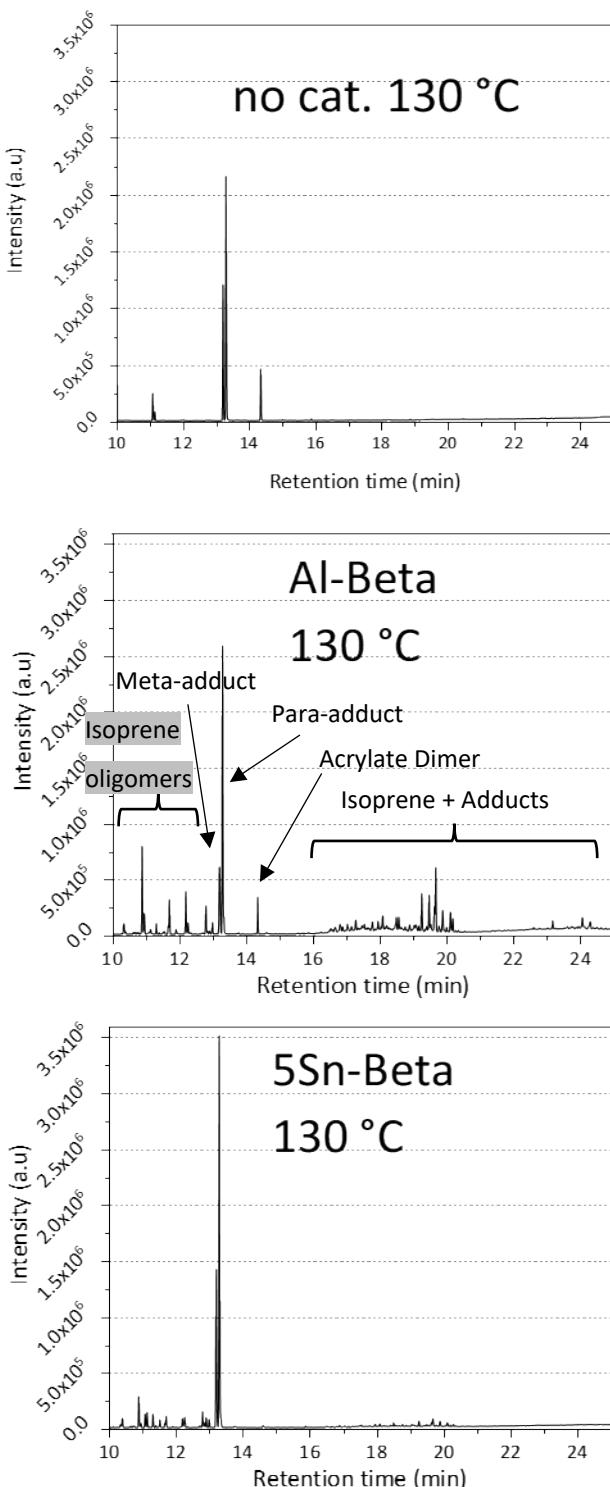

one from  $2330\text{ cm}^{-1}$  to  $2300\text{ cm}^{-1}$  and the other from  $2300\text{ cm}^{-1}$  to  $2260\text{ cm}^{-1}$ . Deconvoluting the first band into component peaks indicate the presence of open ( $2316\text{ cm}^{-1}$ ) and closed ( $2308\text{ cm}^{-1}$ ) Sn-sites.<sup>1</sup> Integrals of absorption bands for open and closed Sn-sites for 2Sn-Beta and 5Sn-Beta suggest that with higher loading, more open Sn-sites are formed. However, while the reaction rate increases with Sn-loading, the catalytic activity per Sn site (TON) is lower for 5Sn-Beta relative to 2Sn-Beta. Therefore, although these results give us the impression that closed Sn-sites are of higher importance for this catalysis, a clear correlation between the nature of the Sn-sites with the activity cannot be drawn. The deconvolution of the second absorption bands from  $2300\text{ cm}^{-1}$  to  $2260\text{ cm}^{-1}$  reveal the presence of  $(\text{SiO})_2\text{Sn(OH)}_2$ -sites ( $2287\text{ cm}^{-1}$ ), silanol groups ( $2275\text{ cm}^{-1}$ ), and residual gas-phase  $\text{CD}_3\text{CN}$  ( $2265\text{ c}^{-1}$ ).<sup>1</sup> The resulting peak for silanol groups at  $2275\text{ cm}^{-1}$  is similar for both 2Sn- and 5Sn-Beta, which is to be expected since both catalysts are prepared from the same starting material and same batch of dealuminated Beta zeolite (D-Beta). Further, peak deconvolution suggests that  $(\text{SiO})_2\text{Sn(OH)}_2$ -sites are significantly dominant in 5Sn-Beta as compared to 2Sn-Beta. A possible explanation for this might be the higher deposition of Sn on the external surface of the zeolite, leading to the formation of highly defective  $(\text{SiO})_2\text{Sn(OH)}_2$ -sites.<sup>1</sup>

**Figure S5.** a) Reaction scheme of main reaction and possible side reactions and b) GC-MS analysis of the product solutions obtained from the reaction using all catalyst at 70 °C, 5 h,  $n_{\text{isoprene}}:n_{\text{methyl acrylate}} = 3$ , 100 mg 70 °C. Significant peaks for desired products and by-products are shown in the GC-MS chromatogram for Al-Beta.

**Figure S6.** GC-MS analysis of the product solution obtained from the reaction using no catalyst, Al-Beta and 5Sn-Beta respectively at 130 °C, 5 h,  $n_{\text{isoprene}}:n_{\text{methyl acrylate}} = 3$ , 100 mg 70 °C. Significant peaks for desired products and by-products are shown in the GC-MS chromatogram for Al-Beta.

**Figure S7.** Computed DA transition state ((R) – para-/exo) structure on the Sn-Beta T8 site. Depicted distances are in picometers. Strong adsorption of methyl acrylate  $\approx$  1 eV. Adsorption of 2nd methyl acrylate  $\approx$  0.7 eV. Additional isoprene adsorption also  $\approx$  0.7 eV.

**Table S1.** Calculated energy barriers for transition states at Sn-Beta T8 site in right handed Beta polymorph A. Lowest energy barriers for each pair of enantiomers are shown in bold.

Transition state coordination	Energy barrier (kJ/mol)
(R) - meta/endo	30
(S) - meta/endo	<b>26</b>
(R) - meta/exo	<b>20</b>
(S) - meta/exo	32
(R) - para/endo	<b>41</b>
(S) - para/endo	57
(R) - para/exo	<b>13</b>
(S) - para/exo	28

**Table S2.** Calculated energy barriers for transition states at Al-Beta T8 site in right handed Beta polymorph A. All four surrounding O-atoms of Al at the T8 site and only transition states leading to the (S)-enantiomer have been considered.

Transition state coordination	o1	o2	o3	o4
(S) - meta/endo	43	<b>35</b>	58	36
(S) - meta/exo	<b>16</b>	38	41	40
(S) - para/endo	50	<b>33</b>	59	34
(S) - para/exo	<b>11</b>	13	32	31

Calculations show a slight preference towards the *para*-adduct on the Al-Beta T8 site in right handed Beta polymorph A, by 5 kJ/mol. Calculation results are in agreement with experimental results, where the use of Al-Beta led to a *para/meta*-ratio of 5.4. Barriers for the *exo* transition states are similar (maximum difference of 4 kJ/mol). When comparing transition states in Al-Beta and Sn-Beta. Differences for *endo* transition states are slightly larger (maximum difference of 8 kJ/mol).

**Table S3.** Periodic PBE-D3 energies and corresponding D3 contribution in eV.
