(S1) X-Ray crystallographic analyses:

Single crystals of complexes **1** were grown from a concentrated solution of toluene in an argon-filled atmosphere at -35 °C. A crystal of suitable dimensions of complexes **1** was mounted on a CryoLoop (Hampton Research Corp.) with a layer of light mineral oil and placed in a nitrogen stream at 100 K. All measurements were made on a Rigaku Supernova X-calibur Eos CCD detector with graphite monochromatic Cu-K α (1.54184 Å) radiation. Crystal data and structure refinement parameters of complexes **1** are summarized in Table TS1. The structures were solved by direct methods (SIR2004)^[1] and refined on F^2 by full-matrix least-squares methods, using SHELXL-97.^[2] Non-hydrogen atoms were anisotropically refined. H-atoms were included in the refinement on calculated positions riding on their carrier atoms. The function minimized was $[\sum w(Fo^2 - Fc^2)^2]$ ($w = 1 / [\sigma^2(Fo^2) + (aP)^2 + bP]$), where $P = (\text{Max}(Fo^2, 0) + 2Fc^2) / 3$ with $\sigma^2(Fo^2)$ from counting statistics. The function $R1$ and $wR2$ were $(\Sigma|Fo| - |Fc|) / \Sigma|Fo|$ and $[\sum w(Fo^2 - Fc^2)^2 / \sum(wFo^4)]^{1/2}$, respectively. A special position disordered toluene molecule was found in the asymmetric unit. The attempts to model the toluene molecule were not successful as it was disordered over more than one position and the refinements were unstable in SHELXL. Contributions to scattering due to this toluene molecule were removed using the solvent mask instruction implemented in Olex2 crystal structure analysis software and squeeze data has been appended at CIF file. The unit cell contains a total of four toluene molecules, each has an area of 175 Å³ and the corresponding electron count was 50. The ORTEP-3 program was used to draw the molecules of **1**. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 2022197 (**1**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK (fax: + (44)1223-336-033; email: deposit@ccdc.cam.ac.uk).

(S3) Experimental details of ester hydroboration:

General procedure for the hydroboration of esters

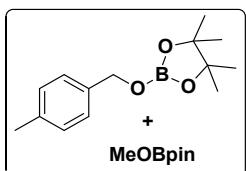

An oven-dried Schlenk flask was charged with 2 mol% catalyst **2** (7.25 mg, 0.01 mmol), required ester precursor (0.50 mmol, 1 equiv) and HBpin (1.0 mmol, 2.0 equiv). The reaction mixture was then placed at room temperature. In the case of solid esters, both the substrate were dissolved in benzene- d_6 (making total volume 1.0 mL). The progress of the reaction was monitored by ^{11}B and ^1H NMR where the product peaks were integrated with respect to the reactant peaks standardized with the $-\text{CH}_3$ - the peak of the internal standard, HMB (8.0 mg, 0.05 mmol) which was normalized to 1.8. After the reaction was completed, the reaction mixture was evaporated under reduced pressure to obtain the desired compounds. Then the residue was washed with *n*-hexane (2×1 mL) to obtain **3a–3v**. Yields were calculated as an isolated yield basis.

(S7) Kinetic analysis details:

Typical NMR-Scale Reaction for determining Kinetic Study by ¹H-NMR Arrays.

Kinetic Analysis. Kinetic analysis of the NMR-scale reactions described above was carried out by collecting multiple (>20) data points. The product concentration was measured from the area of the PhCH₂OBpin peak formed with respect to their starting material peak standardized to the methyl peak area of the C₆Me₆ internal standard. The order of the catalyst and each substrate was determined from the linearity of plots of [product] vs. time (zeroth order), ln[product] vs. time (first-order), and [product]⁻¹ vs. time (second-order) having R² value close towards 1.

[Catalyst] rate order assessment

In a glove box, the respective amount of complex **2** (0.010, 0.015, 0.02, 0.025, 0.03 M), PhCOOMe (0.060g, 0.5 mmol) and HBpin (0.128 g, 1.0 mmol), and the internal standard, hexamethylbenzene (8 mg, 0.05 M), was added in a vial and after that C₆D₆ (1 mL) was added to these reaction mixture. From this stock solution finally, 0.5 mL aliquot were taken out and it was added to a rubber septum-sealed NMR tube, wrapped with parafilm, and removed from the

box. The solution was set in the NMR tube at 25 °C. After that, the tube was shaken and reinserted into the instrument again and scanning was begun. Single (¹H NMR) scans were collected at regular intervals.

Eyring/Arrhenius plots:

Temperature-dependent rate data were obtained *via* arrayed NMR measurement as described above. Temperatures were set on the NMR instrument using an external temperature controller and calibrated using ethylene glycol (>25 °C) or methanol (<25 °C) standards. Rates at each temperature were determined from the average of five trials.

These data were then plotted as $1/T$ vs. $\ln(k/T)$ from which the enthalpy and entropy of the transition state could be obtained using the Eyring equation (see eq. A). ΔH^\ddagger is the negative slope times R and ΔS^\ddagger is the intercept minus the natural log of k_b/h times R. (Figure 82)

$$\ln \frac{k}{T} = \frac{-\Delta H^\ddagger}{R} \cdot \frac{1}{T} + \ln \frac{k_B}{h} + \frac{\Delta S^\ddagger}{R} \quad \text{-----Eq (A)}$$

From a plot of $1/T$ vs. $\ln(k)$, the activation energy can be obtained using the Arrhenius equation (eq. B). E_a is the negative slope times R. (Figure 83)

$$\ln k = -\frac{E_a}{RT} + \ln A \quad \text{-----Eq (B)}$$

(S8) Computational Method:

All calculations were performed using the ORCA quantum chemical program package^[4]. Geometries were optimized with the GGA (generalized gradient approximation) density functional BP86^[5-6] in conjunction with def2-SVP^[7] basis sets. To accelerate the overall calculations, the RI^[8-10] (resolution-of-identity) approximation was applied for the expensive integral calculations. Noncovalent interactions were accounted by using atom-pairwise dispersion corrections with Becke-Johnson (D3BJ) damping.^[11] Subsequent numerical frequency calculations were undertaken for the optimized geometries to confirm that they correspond to stationary points featuring no imaginary frequencies. Gibbs free energies were calculated by single point calculations with BP86/def2-TZVP^[7] method on the BP86/def2-SVP geometries.

(S9) Discussion on D \rightarrow I Conversion: Key Conformational Changes in Ti–O_aCH(CH₃)O_bCH₃ Fragment :

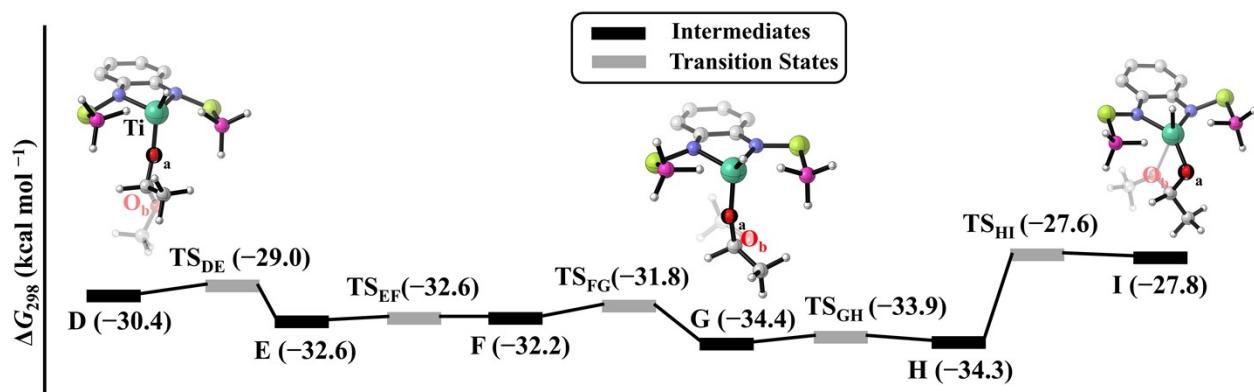

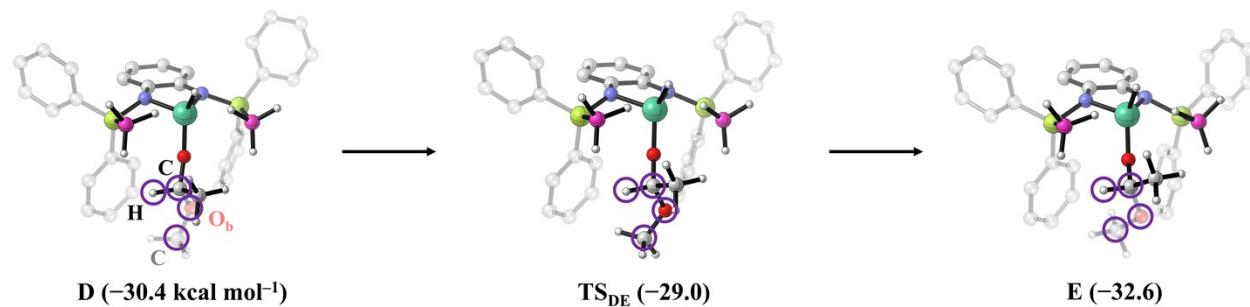

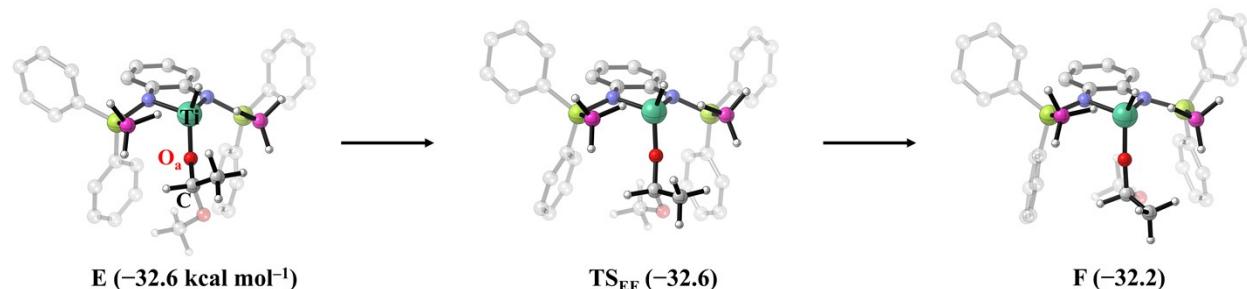

Figure S85. D \rightarrow I conversion. Conformational changes occur in the Ti-coordinated CH₃C(O_a)(O_b)CH₃ unit. BP86-D3/def2-TZVP // BP86-D3/def2-SVP is used. Gibbs free energies ΔG_{298} [kcal mol⁻¹] are relative to A.

S9.1. D \rightarrow TS_{DE} \rightarrow E: Rotation Around C–O_b Bond

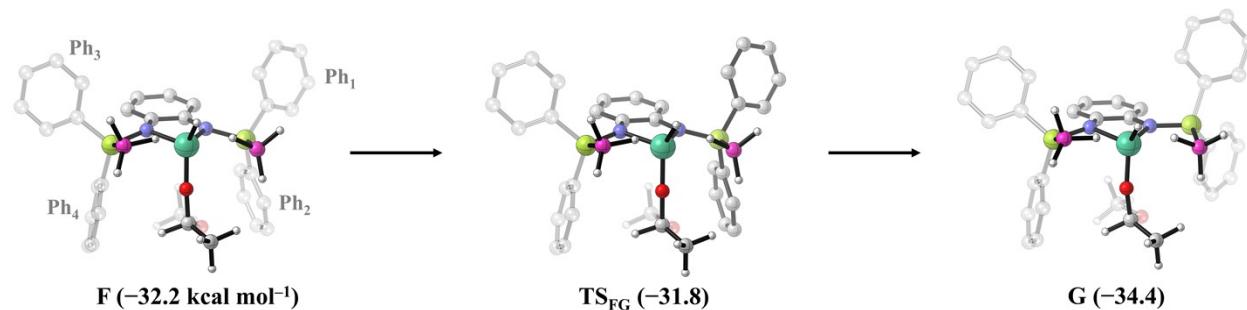

The intermediate **D** is connected to the transition state **TS_{DE}** involving rotation along C–O_b with a minute activation barrier of 1.4 kcal mol⁻¹ to give intermediate **E**. The dihedral angle H–C–O_b–C is -40.44° in **D**, -12.21° in **TS_{DE}** and 45.05° in **E**, respectively which clearly indicate the rotation around $-\text{O}_b\text{CH}_3$ fragment.

S9.2. E→TS_{EF}→F: Change in Ti–O_a–C Angle

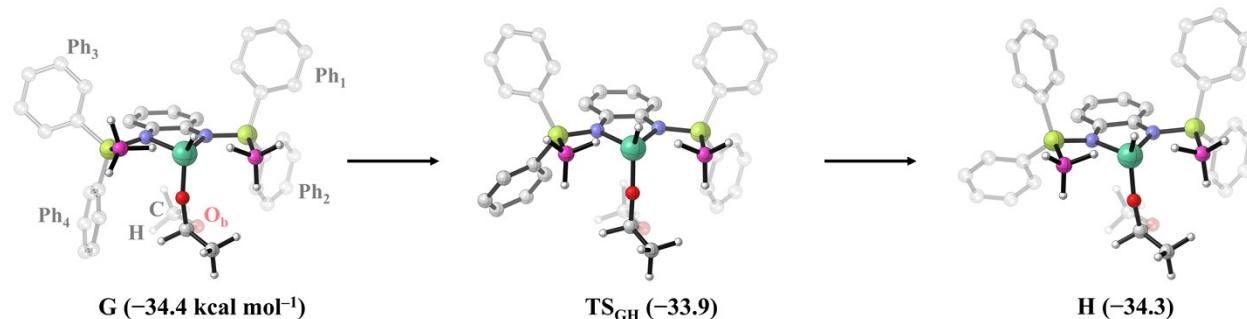

Intermediate **E** undergoes an inward rotation in $\text{CH}_3\text{CH}(\text{O}_a)(\text{O}_b)\text{CH}_3$ fragment through **TS_{EF}** with a minute activation barrier of 0.1 kcal mol⁻¹ to produce **F**. This rotation is evidenced by the change in angle of Ti–O_a–C which is 142.37° in **E**, 168.75° in **TS_{EF}** and 199.98° in **F**, respectively.

S9.3. F→TS_{FG}→G: Rotation in Phenyl Rings

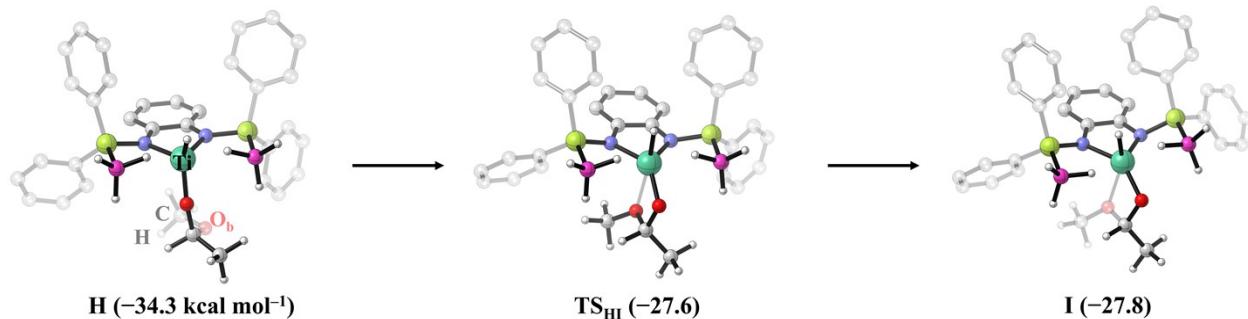

Intermediate **F** is connected to **G** via transition state **TS_{FG}** in which a slight rotation in phenyl rings Ph₁ and Ph₂ takes place leading to an activation barrier of merely 0.44 kcal mol⁻¹. Due to this rotation, these phenyl rings are now oriented in such a way that there is less steric hindrance.

S9.4. G→TS_{GH}→H: Rotation in Phenyl Ring

Intermediate **G** undergoes rotation in phenyl ring Ph_4 via TS_{GH} with an activation barrier of only 0.5 kcal mol⁻¹ to produce **H**. Now, the orientation of all phenyl rings allows the free rotation of $(\text{O}_b)\text{CH}_3$ group in the next intermediates and transition states.

S9.5. $\text{H} \rightarrow \text{TS}_{\text{HI}} \rightarrow \text{I}$: Rotation of $(\text{O}_b)\text{CH}_3$ Group

Now, due to rotation of $(\text{O}_b)\text{CH}_3$ group in intermediate **H** via TS_{HI} , coordination of methoxy oxygen (O_b) takes place and leads to the formation of a less stable intermediate **I** (in comparison with **H**). The activation barrier for this conversion is 6.7 kcal mol⁻¹. The $\text{Ti}-\text{O}_b$ distance is 3.53 Å in **H**, 2.41 Å in TS_{HI} and 2.23 Å in **I** are in line with observation of coordination of O_b to Ti centre.

(S10) Discussion on $\text{J} \rightarrow \text{O}$ Conversion: Key Changes in Acetaldehyde Orientation Around the Ti Center :

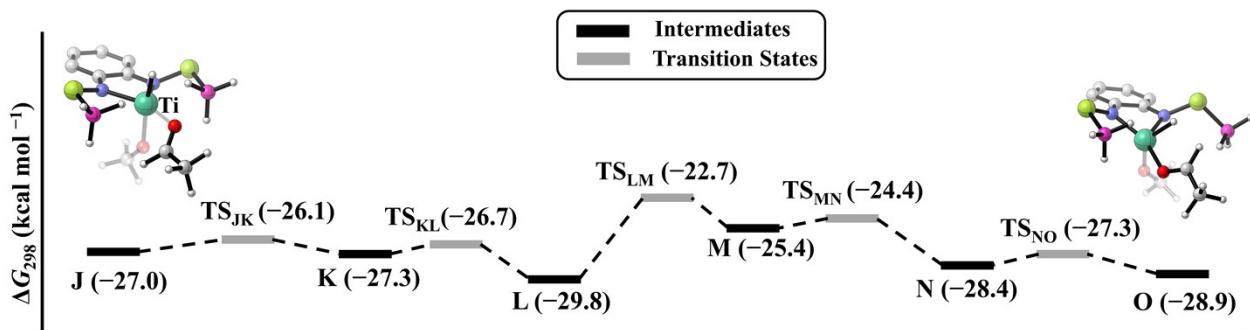

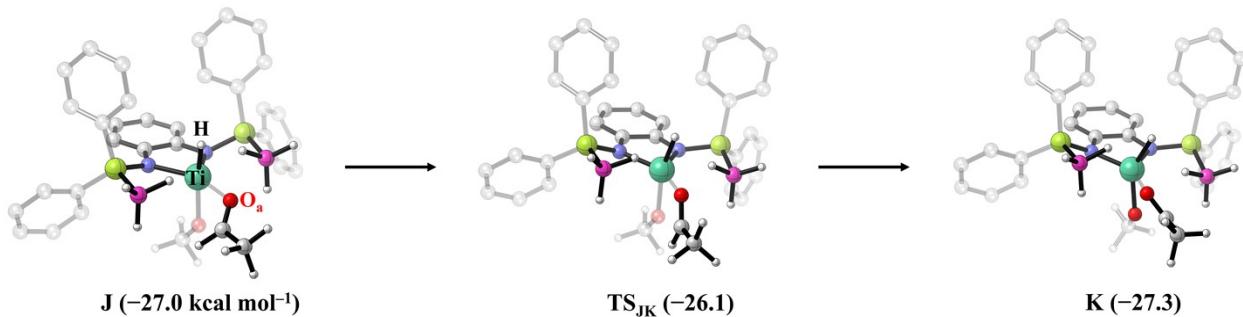

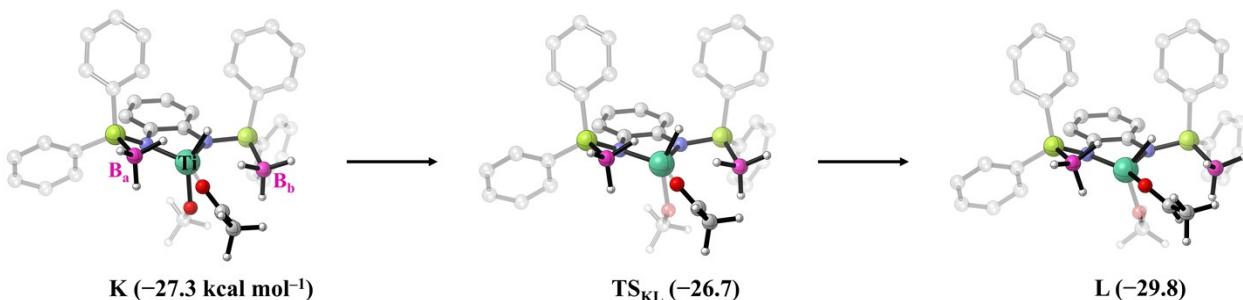

Figure S8. $\text{J} \rightarrow \text{O}$ conversion. Changes in acetaldehyde orientation around the Ti center. BP86-D3/def2-TZVP // BP86-D3/def2-SVP is used. Gibbs free energies ΔG_{298} [kcal mol⁻¹] are relative to **A**.

S10.1. $\text{J} \rightarrow \text{TS}_{\text{JK}} \rightarrow \text{K}$: Rotation Around $\text{Ti}-\text{O}_a$ Bond

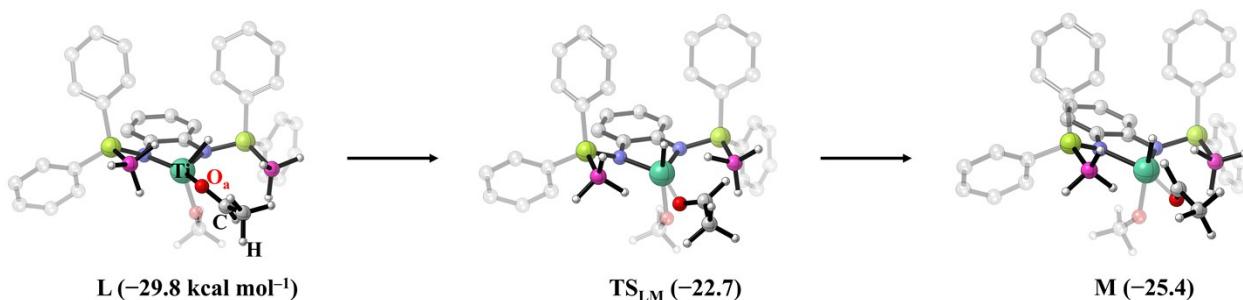

The second intramolecular hydride transfer to carbonyl carbon does not take place until hydride and carbonyl carbon are on the same plane. In intermediate **J**, hydride and carbonyl carbon are in opposite planes. That is the reason, in intermediate **J**, the rotation of $\text{CH}_3\text{C}(\text{O}_a)\text{H}$ fragment around $\text{Ti}-\text{O}_a$ bond occurs via **TS_{JK}** with the activation barrier of only 0.9 kcal mol⁻¹ and leads to intermediate **K**. However, this rotational step is not enough to make them in the same plane.

S10.2. **K**→**TS_{KL}**→**L**: Change in Nonbonding $\text{Ti}-\text{B}_a$ Distance

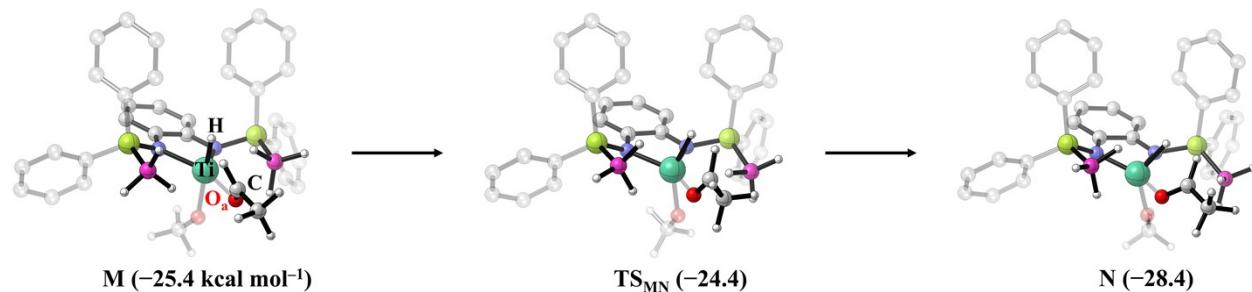

Intermediate **K** is connected to **L** via **TS_{KL}** with the activation barrier of only 0.6 kcal mol⁻¹. The structure of **TS_{KL}** shows a small increase in nonbonding $\text{Ti}-\text{B}_a$ distance from 3.08 Å upto 3.09 Å, whereas this distance of 3.57 Å is found in **L**. The increase in this distance will allow further rotation of $\text{CH}_3\text{C}(\text{O}_a)\text{H}$ fragment around $\text{Ti}-\text{O}_a$ bond.

S10.3. **L**→**TS_{LM}**→**M**: Rotation Around $\text{Ti}-\text{O}_a$ Bond

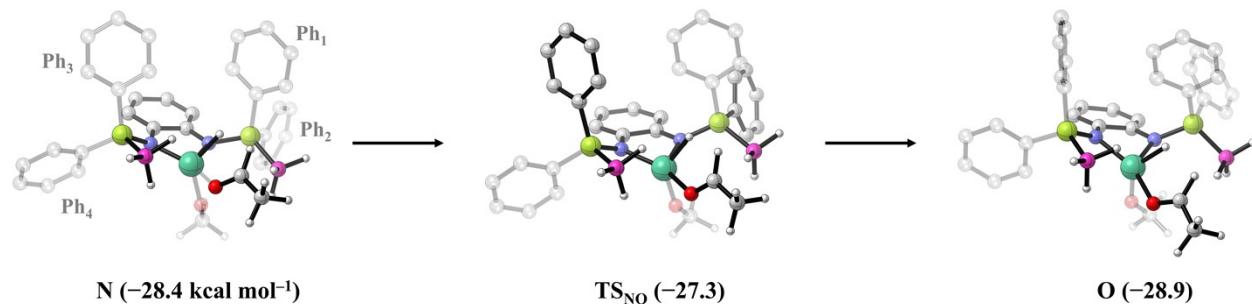

In intermediate **L**, rotation of $\text{CH}_3\text{C}(\text{O}_a)\text{H}$ fragment around $\text{Ti}-\text{O}_a$ bond occurs via **TS_{LM}** to produce **M** with an activation barrier of 7.1 kcal mol⁻¹.

S10.4. M→TS_{MN}→N: Change in dihedral Angle in H–Ti–(O)_a–CHCH₃

Intermediate **M** is connected to **N** via a transition state **TS_{MN}** with an activation barrier of 1 kcal mol⁻¹. The transition state involves the change in dihedral angle in H–Ti–(O)_a–CHCH₃ around Ti–O_a bond. Now, hydride and carbonyl carbon are in one plane for hydride transfer.

S10.5. N→TS_{NO}→O: Rotation in Phenyl Ring

Before hydride transfer to the carbonyl carbon, there is a rotation in Ph₃ (phenyl ring) in **N** connected to **O** via **TS_{NO}** with an activation barrier of 1.1 kcal mol⁻¹. Now, in the subsequent step, there will be a second intramolecular hydride transfer.
