## EXPERIMENTAL

## Materials and Methods

All syntheses were performed under argon or nitrogen using standard Schlenk techniques. Anhydrous tetrahydrofuran, dichloromethane and methanol were obtained from an in-house PureSolv MD5 Solvent Purification System (Innovative Technology, Inc., USA). Anhydrous acetonitrile was obtained by distillation from calcium hydride and stored under nitrogen. $\operatorname{Gold}(\mathrm{I})$ complexes $\left[\mathrm{Au}(\mathrm{tht})_{2}\right]\left[\mathrm{SbF}_{6}\right]$ (tht $=$ tetrahydrothiophene; the perchlorate salt was obtained analogously), ${ }^{1}\left[\mathrm{AuCl}\left(\mathrm{FcPPh}_{2}\right)\right]^{2}\left(\mathrm{Fc}=\right.$ ferrocenyl), $\left[\mathrm{AuCl}\left(\mathrm{PCy}_{3}\right)\right]^{3}$ and 1-bromo-1'(diphenylphosphino)ferrocene ${ }^{4}$ were prepared according to literature procedures (complex $\left[\mathrm{AuCl}\left(\mathrm{PPh}_{3}\right)\right]$ was obtained similarly to $\left.\left[\mathrm{AuCl}\left(\mathrm{FcPPh}_{2}\right)\right]\right)$. The remaining reagents were purchased from commercial suppliers (Sigma-Aldrich and TCI) and used as received.

NMR spectra were recorded at $25^{\circ} \mathrm{C}$ on a Bruker AVANCE III 600 spectrometer $\left({ }^{1} \mathrm{H}\right.$, $600.17 \mathrm{MHz},{ }^{13} \mathrm{C}, 150.93 \mathrm{MHz}$ ) or on a Varian UNITY Inova 400 spectrometer ( ${ }^{1} \mathrm{H}, 399.95 \mathrm{MHz}$, ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}, 100.58 \mathrm{MHz},{ }^{19} \mathrm{~F}, 376.29 \mathrm{MHz},{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}, 161.90 \mathrm{MHz}$ ). Chemical shifts ( $\delta / \mathrm{ppm}$ ) are given relative to internal tetramethylsilane ( ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C} \mathrm{NMR}$ ), to external $85 \%$ aqueous $\mathrm{H}_{3} \mathrm{PO}_{4}$ ( ${ }^{31} \mathrm{P}$ NMR) and to neat trichlorofluoromethane ( ${ }^{19} \mathrm{~F}$ NMR). Electrospray-ionisation mass spectra were recorded in positive-ion mode. Low resolution spectra were recorded on an Esquire 3000 spectrometer (Bruker), while high resolution spectra were obtained using either a Compact QTOF-MS spectrometer (Bruker) or a LTQ Orbitrap XL instrument (Thermo Scientific). The identity of the ionic species was confirmed by comparing theoretical and experimentally determined isotopic patterns. Elemental analyses were performed on a Perkin-Elmer PE 2400 CHN analyser.

## Syntheses

Synthesis of $\left[\left(\mathrm{Ph}_{2} \mathbf{P f c A u}\right)_{2}\right]$ (1, fc $=$ ferrocene-1,1'-diyl). 1-Bromo-1'-(diphenylphosphino)ferrocene ( $898 \mathrm{mg}, 2.0 \mathrm{mmol}$ ) was introduced to a flame-dried three-necked flask ( 250 mL ) equipped with a magnetic stirring bar, an argon inlet and a solid addition tube charged with $\left[\mathrm{AuCl}\left(\mathrm{SMe}_{2}\right)\right](589 \mathrm{mg}, 2.0 \mathrm{mmol})$. The reaction vessel was thoroughly purged with argon, and the ferrocene precursor was dissolved in anhydrous tetrahydrofuran ( 20 mL ). The solution was cooled to $-78{ }^{\circ} \mathrm{C}$ in a dry ice/ethanol bath and treated with $n$-BuLi in hexane ( 0.8 mL of 2.5 M solution, 2.0 mmol$)$. After stirring for 1 hour at $-78{ }^{\circ} \mathrm{C},\left[\mathrm{AuCl}\left(\mathrm{SMe}_{2}\right)\right]$ was added to the solution from the solid addition tube, and the reaction mixture was stirred for another 30 min at $-78^{\circ} \mathrm{C}$ and then allowed to warm to room temperature overnight. The solvents were evaporated on a
rotary evaporator, and the solid residue was extracted with two portions of dichloromethane ( 50 mL in total). The organic extracts were filtered through a short Celite pad, and the filtrate was concentrated to ca. 10 mL . The solution was transferred to a test tube and layered with acetonitrile. The crystalline material obtained overnight was isolated by decantation, washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and diethyl ether and dried under vacuum. Yield 945 mg ( $83 \%$ ), orange crystals.
${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}, 399.95 \mathrm{MHz}$ ): $\delta=4.17$ ( $\mathrm{vq}, ~ J=1.4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc), 4.38 (d of vt, $J=2.7$, $1.8 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc), 4.43 (vt of d, $J=1.9,0.9 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc), $4.45(\mathrm{vq}, J=1.5 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc), 7.28-7.39 (m, $12 \mathrm{H}, \mathrm{PPh}_{2}$ ), 7.66-7.74 (m, $8 \mathrm{H}, \mathrm{PPh}_{2}$ ) ppm. ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 100.58 \mathrm{MHz}\right): \delta=$ $69.92\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PC}}=6 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc$), 70.32\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PC}}=62 \mathrm{~Hz}\right.$, Cipso-P of fc), $71.05\left(\mathrm{~d}, J_{\mathrm{PC}}=8 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $72.41\left(\mathrm{~d}, J_{\mathrm{PC}}=13 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $79.16\left(\mathrm{~d}, J_{\mathrm{PC}}=5 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $103.94\left(\mathrm{~d},{ }^{2} \mathrm{~J}_{\mathrm{PC}}=125 \mathrm{~Hz}, \mathrm{Cipso}^{2}-\mathrm{Au}\right.$ of fc), $128.21\left(\mathrm{~d}, J_{\mathrm{PC}}=10 \mathrm{~Hz}, \mathrm{CH}\right.$ of $\mathrm{PPh}_{2}$ ), $130.11\left(\mathrm{~d},{ }^{4} \mathrm{~J}_{\mathrm{PC}}=2 \mathrm{~Hz}, \mathrm{CH}^{\text {para }}\right.$ of $\mathrm{PPh}_{2}$ ), $133.78\left(\mathrm{~d},{ }^{1} \mathrm{~J}_{\mathrm{PC}}=50\right.$ Hz, Cipso -P of $\mathrm{PPh}_{2}$ ), $133.80\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PC}}=13 \mathrm{~Hz}, \mathrm{CH}\right.$ of $\left.\mathrm{PPh}_{2}\right) \mathrm{ppm} .{ }^{31}{ }^{31}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 161.90 \mathrm{MHz}\right): \delta$ $=40.5$ (s) ppm. HR ESI + MS: $m / z=1132.032\left(\mathrm{M}^{+}\right)$. Anal. Calc. for $\mathrm{C}_{44} \mathrm{H}_{36} \mathrm{Au}_{2} \mathrm{Fe}_{2} \mathrm{P}_{2}$ (1132.3): C 46.67, H 3.20\%. Found: C 46.42, H 3.04\%.

Preparation of $\left[\left(\mathbf{P h}_{2} \mathbf{P f c A u}\right)_{2}\left\{\mathbf{A u}\left(\mathbf{F c P P h}_{2}\right)\right\}_{2}\right]\left[\mathbf{S b F}_{6}\right]_{2} \mathbf{( 2 )}$. A solution of $\left[\mathrm{AuCl}\left(\mathrm{FcPPh}_{2}\right)\right]$ ( $60.2 \mathrm{mg}, 0.10 \mathrm{mmol}$ ) in dichloromethane ( 5 mL ) was combined with an acetonitrile solution of $\mathrm{Ag}\left[\mathrm{SbF}_{6}\right]$ ( $34.3 \mathrm{mg}, 0.10 \mathrm{mmol}$ in 2 mL of the solvent), whereupon a white precipitate ( AgCl ) separated. The reaction mixture was stirred for 15 minutes, filtered through a PTFE syringe filter ( $0.45 \mu \mathrm{~m}$ pore size), and the filtrate was evaporated to dryness. The solid residue was taken up with dichloromethane ( 3 mL ) and filtered again through syringe filter to remove residual AgCl . The filtrate was mixed with a solution of $\mathbf{1}(56.6 \mathrm{mg}, 0.050 \mathrm{mmol})$ in dichloromethane ( 10 mL ) whereupon the reaction mixture turned from orange to red. After stirring for 1 hour, the mixture was filtered through Celite and evaporated to dryness to give $\mathbf{2}$. Yield: 129 mg (94\%), pale red powdery solid. Crystals suitable for structure determination were obtained by slow diffusion of diethyl ether into a dichloromethane solution of the complex.
${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{OD}, 399.95 \mathrm{MHz}$ ): $\delta=3.77-3.90(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}$ of fc), $4.01(\mathrm{~s}, 10 \mathrm{H}, \mathrm{CH}$ of fc), 4.09-4.63 (m, $14 \mathrm{H}, \mathrm{CH}$ of fc), 4.82-5.09 (m, $6 \mathrm{H}, \mathrm{CH}$ of fc), 6.17-6.35 (m, $2 \mathrm{H}, \mathrm{CH}$ of fc), 6.85$7.09\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{PPh}_{2}\right), 7.16-7.81\left(\mathrm{~m}, 36 \mathrm{H}, \mathrm{PPh}_{2}\right) \mathrm{ppm} .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{OD}, 161.90 \mathrm{MHz}\right): \delta$ $=31.9\left(\mathrm{~d}, J_{\mathrm{PP}}=4 \mathrm{~Hz}, \mathrm{fcPPh}_{2}\right), 35.5\left(\mathrm{~d}, J_{\mathrm{PP}}=4 \mathrm{~Hz}, \mathrm{FcPPh}_{2}\right) \mathrm{ppm}$. HR ESI $+\mathrm{MS}: m / z=1133.039([\mathrm{M}-$ $2 \mathrm{SbF}_{6}{ }^{2+}$ ). Anal. Calc. for $\mathrm{C}_{88} \mathrm{H}_{74} \mathrm{Au}_{4} \mathrm{~F}_{12} \mathrm{Fe}_{4} \mathrm{P}_{4} \mathrm{Sb}_{2}$ (2738.2): C 38.60, H $2.72 \%$. Found: C 38.69, H 2.76\%.

Preparation of $\left[\left\{\left(\mathbf{P h}_{2} \mathbf{P f c A u}\right)_{2}\left\{\mathbf{A u}\left(\mathbf{P C y}_{3}\right)\right\}_{2}\right]\left[\mathbf{S b F}_{6}\right]_{2} \mathbf{( 3 )}\right.$. A solution of $\left[\mathrm{AuCl}\left(\mathrm{PCy}_{3}\right)\right](51.3$ $\mathrm{mg}, 0.10 \mathrm{mmol}$ ) in dichloromethane ( 5 mL ) was combined with an acetonitrile solution of $\mathrm{Ag}\left[\mathrm{SbF}_{6}\right]$ ( $34.3 \mathrm{mg}, 0.10 \mathrm{mmol}$ in 3 mL ). The reaction mixture was stirred for 30 minutes to complete AgCl precipitation and filtered through a PTFE syringe filter, and the filtrate was evaporated to dryness. The white solid residue was redissolved in dichloromethane ( 5 mL ) and
the solution filtered through a syringe filter to completely remove AgCl . The resulting clear solution was added to an orange solution of $\mathbf{1}(56.6 \mathrm{mg}, 0.050 \mathrm{mmol})$ in dichloromethane ( 10 mL ), yielding a red reaction mixture. After stirring for 1 hour, the clear mixture was filtered through Celite and evaporated thoroughly to dryness, resulting in 3. Yield: 126 mg ( $98 \%$ ), pale red solid. Crystals suitable for structure determination were grown by liquid-phase diffusion of fluorobenzene to a dichloromethane solution of the complex.
${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{NO}_{2}, 399.95 \mathrm{MHz}$ ): $\delta=1.09-1.22(\mathrm{~m}, 6 \mathrm{H}, \mathrm{PCy} 3$ ), 1.23-1.52 (m, 20 H , РСуз), 1.65-1.84 (m, 26 H, РСуз), 1.94-2.05 (m, 10 H, РСуз), 2.14-2.26 (m, 4 Н, РСуз), 5.20-5.27 (br s, $2 \mathrm{H}, \mathrm{CH}$ of fc), 7.47-7.75 (m, $20 \mathrm{H}, \mathrm{PPh}_{2}$ ) ppm. Signals due to remaining ferrocene protons were not observed due to extensive broadening. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{NO}_{2}, 161.90 \mathrm{MHz}\right): \delta=$ 31.5 (d, ${ }^{3}{ }_{\mathrm{JPP}}=3 \mathrm{~Hz}, \mathrm{PPh}_{2}$ ), $61.4\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{PP}}=3 \mathrm{~Hz}, \mathrm{PCy}\right)$ ) ppm. HR ESI $+\mathrm{MS}: m / z=1043.216$ ([M $\left.2 \mathrm{SbF}_{6}\right]^{2+}$ ). Anal. Calc. for $\mathrm{C}_{80} \mathrm{H}_{102} \mathrm{Au}_{4} \mathrm{~F}_{12} \mathrm{Fe}_{2} \mathrm{P}_{4} \mathrm{Sb}_{2}$ (2558.6): C 37.55, H 4.02\%. Found: C 37.98, H 4.04\%.

Preparation of $\left[\left\{\left(\mathbf{P h}_{2} \mathbf{P f c A u}\right)_{2}\left\{\mathbf{A u}\left(\mathbf{P P h}_{3}\right)\right\}_{2}\right]\left[\mathbf{S b F}_{6}\right]_{2} \mathbf{( 4 )}\right.$. A solution of $\left[\mathrm{AuCl}^{\left.\left(\mathrm{PPh}_{3}\right)\right](49.5}\right.$ $\mathrm{mg}, 0.10 \mathrm{mmol}$ ) in dichloromethane ( 5 mL ) was mixed with an acetonitrile solution of $\mathrm{Ag}\left[\mathrm{SbF}_{6}\right.$ ] ( $34.3 \mathrm{mg}, 0.10 \mathrm{mmol}$ in 3 mL ), whereupon AgCl separated as an off-white solid. The reaction mixture was stirred for 30 minutes and then filtered through PTFE syringe filter. The solvents were removed under reduced pressure, and the solid residue was redissolved in dichloromethane ( 5 mL ). The resulting cloudy solution was filtered once again and then mixed with a solution of $\mathbf{1}$ ( $56.6 \mathrm{mg}, 0.050 \mathrm{mmol}$ ) in dichloromethane ( 10 mL ). After stirring for 1 hour, the reaction mixture was filtered through Celite and carefully evaporated to give 4. Yield: 119 mg ( $94 \%$ ), red powdery solid. The purity of this sample exceeded $90 \%$. The major contaminants, present inherently and inevitably, are the hexagold cluster $\mathbf{5}$ and the side product of the $\mathbf{4} \rightarrow \mathbf{5}$ conversion, complex $\left[\mathrm{Au}\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{SbF}_{6}\right] .{ }^{[5]}$
${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CD}_{2} \mathrm{Cl}_{2}, 399.95 \mathrm{MHz}$ ): $\delta=4.07$ (br s, $2 \mathrm{H}, \mathrm{CH}$ of fc), $4.20(\mathrm{br} \mathrm{s}, 2 \mathrm{H}, \mathrm{CH}$ of fc), 4.30 (br s, $2 \mathrm{H}, \mathrm{CH}$ of fc), 4.62-4.75 (m, $4 \mathrm{H}, \mathrm{CH}$ of fc), 4.86 ( $\mathrm{br} \mathrm{s}, 2 \mathrm{H}, \mathrm{CH}$ of fc), 5.26 (br s, $2 \mathrm{H}, \mathrm{CH}$ of fc), 6.18 (br s, $2 \mathrm{H}, \mathrm{CH}$ of fc), 6.96-7.10 (m, $4 \mathrm{H}, \mathrm{PPh}_{2}$ ), 6.25-7.70 (m, $46 \mathrm{H}, \mathrm{PPh}_{2}$ ) ppm. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 161.90 \mathrm{MHz}\right): \delta=31.9\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{PP}}=4 \mathrm{~Hz}, \mathrm{PPh}_{2}\right), 39.0\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{PP}}=4 \mathrm{~Hz}, \mathrm{PPh}_{3}\right) \mathrm{ppm}$. ESI $+\mathrm{MS}: m / \mathrm{z}$ $=1025.3\left(\left[\mathrm{M}-2 \mathrm{SbF}_{6}\right]^{2+}\right)$. Anal. Calc. for $\mathrm{C}_{80} \mathrm{H}_{66} \mathrm{Au}_{4} \mathrm{~F}_{12} \mathrm{Fe}_{2} \mathrm{P}_{4} \mathrm{Sb}_{2}$ (2522.3): C 38.09, H 2.64\%. Found: C 37.99, H 2.55\%.

Preparation of $\left[\left\{\left(\mathbf{P h}_{2} \mathbf{P f c A u}\right)_{2} \mathbf{A u}\right\}_{2}\right]\left[\mathbf{S b F}_{6}\right]_{2}$ (5). Solid $\left[\mathrm{Au}(\mathrm{tht})_{2}\right]\left[\mathrm{SbF}_{6}\right]$ ( $30.5 \mathrm{mg}, 0.050$ $\mathrm{mmol})$ was added to a solution of $\mathbf{1}(56.6 \mathrm{mg}, 0.050 \mathrm{mmol})$ in dichloromethane ( 10 mL ). The reaction mixture turned red and became turbid. After stirring for 1 hour, the solvents were removed under reduced pressure. The solid residue was taken up with dichloromethane ( 5 mL ) and filtered through short Celite pad, and the filtrate was added slowly to diethyl ether ( 20 mL ). The precipitate was isolated by decantation, washed with diethyl ether and dried under vacuum.

Yield of 5: 66 mg ( $85 \%$ ), red microcrystalline compound. Note: the same compound was obtained during attempted crystalisation of 4 from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$-acetonitrile/diethyl ether or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ THF/diethyl ether mixtures.
${ }^{1} \mathrm{H}$ NMR ( $\left.\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{OD}, 399.95 \mathrm{MHz}\right): \delta=3.93$ (t of vt, $J=2.7 \mathrm{~Hz}, 1.4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc ), 4.25 ( d of $\mathrm{vt}, J=2.6,1.0 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc ), 4.34 ( t of $\mathrm{vt}, J=2.6 \mathrm{~Hz}, 1.4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc ), 4.87 ( vt of $\mathrm{d}, J=2.6,1.2 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc ), 5.13-5.17 (m, $8 \mathrm{H}, \mathrm{CH}$ of fc), 5.31-5.33(m, $4 \mathrm{H}, \mathrm{CH}$ of fc), 6.11 (t of $\mathrm{vt}, J=2.7 \mathrm{~Hz}, 1.4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}$ of fc), $7.39-7.62\left(\mathrm{~m}, 40 \mathrm{H}, \mathrm{PPh}_{2}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{OD}\right.$, 100.58 MHz ): $\delta=66.55\left(\mathrm{~d},{ }^{1} \mathrm{~J}_{\mathrm{PC}}=64 \mathrm{~Hz}\right.$, Cipso-P of fc), $66.82\left(\mathrm{dd}, \mathrm{J}_{\mathrm{PC}}=18,7 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc ), $73.94(\mathrm{~d}$, $J_{\mathrm{PC}}=9 \mathrm{~Hz}, \mathrm{CH}$ of fc ), $74.30\left(\mathrm{~d}, J_{\mathrm{PC}}=6 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $76.34\left(\mathrm{~d},{ }^{1} J_{\mathrm{PC}}=57 \mathrm{~Hz}\right.$, Cipso-Au of fc), $77.53(\mathrm{~d}$, $J_{\mathrm{PC}}=3 \mathrm{~Hz}, \mathrm{CH}$ of fc ), $77.98\left(\mathrm{~d}, J_{\mathrm{PC}}=4 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $78.36\left(\mathrm{~d}, J_{\mathrm{PC}}=5 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc), $85.22(\mathrm{~s}, \mathrm{CH} \mathrm{of} \mathrm{fc})$, $91.06\left(\mathrm{t}, J_{\mathrm{PC}}=3 \mathrm{~Hz}, \mathrm{CH}\right.$ of fc$), 128.53\left(\mathrm{~d},{ }^{1} J_{\mathrm{PC}}=56 \mathrm{~Hz}, \mathrm{C}^{\mathrm{ipso}}-\mathrm{P}\right.$ of $\left.\mathrm{PPh}_{2}\right), 130.08\left(\mathrm{~d}, J_{\mathrm{PC}}=11 \mathrm{~Hz}, \mathrm{CH}\right.$ of $\left.\mathrm{PPh}_{2}\right), 130.12\left(\mathrm{~d}, J_{\mathrm{PC}}=12 \mathrm{~Hz}, \mathrm{CH}\right.$ of $\left.\mathrm{PPh}_{2}\right), 132.35\left(\mathrm{~d},{ }^{4} \mathrm{JPC}=3 \mathrm{~Hz}, \mathrm{CH}^{\text {para }}\right.$ of $\left.\mathrm{PPh}_{2}\right), 132.40\left(\mathrm{~d}, J_{\mathrm{PC}}=14\right.$ $\mathrm{Hz}, \mathrm{CH}$ of $\mathrm{PPh}_{2}$ ), $132.96\left(\mathrm{~d},{ }^{4} \mathrm{~J}_{\mathrm{PC}}=2 \mathrm{~Hz}, \mathrm{CH}\right.$ para of $\mathrm{PPh}_{2}$ ), $133.06\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PC}}=51 \mathrm{~Hz}, \mathrm{C}^{\text {ipsoo- }}\right.$ of $\mathrm{PPh}_{2}$ ), $135.40\left(\mathrm{~d}, J_{\mathrm{PC}}=15 \mathrm{~Hz}, \mathrm{CH}\right.$ of $\left.\mathrm{PPh}_{2}\right)$ ppm. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}+\mathrm{CD}_{3} \mathrm{OD}, 161.90 \mathrm{MHz}\right): \delta=31.8(\mathrm{~s})$ ppm. HR ESI+ MS: $m / z=1329.000\left(\left[\mathrm{M}-2 \mathrm{SbF}_{6}\right]^{2+}\right)$. Anal. Calc. for $\mathrm{C}_{88} \mathrm{H}_{72} \mathrm{Au}_{6} \mathrm{~F}_{12} \mathrm{Fe}_{4} \mathrm{P}_{4} \mathrm{Sb}_{2}$ (3130.1): C 33.77, H 2.32\%. Found: C 33.73, H 2.18\%.

Preparation of $\left[\left\{\left(\mathrm{Ph}_{2} \mathrm{PfcAu}\right)_{2} \mathbf{A u}\right\}_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2} \mathbf{( 5 a )}$. Method A: Compound $\mathbf{1}$ (56.6 mg, $0.050 \mathrm{mmol})$ and $\left[\mathrm{AuCl}\left(\mathrm{PPh}_{3}\right)\right](49.4 \mathrm{mg}, 0.10 \mathrm{mmol})$ were dissolved in dichloromethane ( 5 mL ). $\mathrm{AgClO}_{4}$ ( $20.7 \mathrm{mg}, 0.10 \mathrm{mmol}$ ) dissolved in the same solvent ( 2 mL ) was added and the reaction mixture was stirred for 1 hour, during which time it deposited a dark solid and changed colour from orange to red. The precipitated AgCl was removed by filtration through a PTFE syringe filter, and the filtrate was evaporated to dryness under vacuum. Subsequent recrystallisation of the crude product by liquid-phase diffusion of tert-butyl methyl ether into a dichloromethaneacetonitrile solution (3:1, v/v) produced red crystals, which were isolated by decantation, washed with diethyl ether and dried under vacuum. Yield of 5a: 55 mg (77\%), red crystals.

Method B: A solution of $1(56.6 \mathrm{mg}, 0.050 \mathrm{mmol})$ in dichloromethane ( 10 mL ) was combined with a solution of $\left[\mathrm{Au}(\mathrm{tht})_{2}\right]\left[\mathrm{ClO}_{4}\right](23.6 \mathrm{mg}, 0.050 \mathrm{mmol})$ in the same solvent ( 5 mL ). The colour of the reaction mixture changed immediately from orange to red. The mixture was stirred for 1 hour and evaporated under reduced pressure. The crude product was dissolved in dichloromethane ( 5 mL ), and the solution was filtered through a short Celite pad. The filtrate was evaporated to dryness, and the resulting solid was suspended in diethyl ether ( 20 mL ) and briefly sonicated to remove residual tetrahydrothiophene. The product was then isolated by decantation and dried under vacuum. Yield of 5a: 70 mg ( $98 \%$ ), red powder.

## DFT COMPUTATIONS

Density Functional Theory computations were performed using Gaussian16, Revision C.01. ${ }^{[6]}$ All cationic species were first symmetrized to point group $D_{2}$ and subsequently optimised by imposing no geometry constraints during the optimisation stage. All computations utilised the M06 functional, ${ }^{7}$ the Stuttgart-Dresden core potentials ${ }^{8}$ for the $\mathrm{Au}, \mathrm{Ag}, \mathrm{Cu}$ and Fe atoms and the $6-311 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set for all remaining atoms. Empirical dispersion was accounted for by including the Grimme D3 damping function. ${ }^{9}$ The Hessians needed for geometry optimisations were estimated before the initial optimisation steps. Natural Bonding Orbital studies were performed using the standalone version of NBO6. ${ }^{10}$ Nuclear Independent Chemical Shifts (NICS) were computed for dummy atoms placed at the centroids of the consituted by the group 11 atoms using the Gauge Independent Atomic Orbital (GIAO) approach. ${ }^{11}$ Molar volumes were computed using $0.001 \mathrm{e} \mathrm{bohr}^{-3}$ density envelopes for the Monte-Carlo integrations.

## Description of the bonding situation in 5

The DFT-optimised complex cation in 5 has a symmetry of the $D_{2}$ point group (Figure S1), whose origin is located at the centroid of the hexagold ring. Hence, the six atoms of this ring can be subdivided into two symmetrically inequivalent groups - the first incorporating four Au atoms with a coordinated phosphine moiety (Au1, Au3, Au4 and Au6) and the second group including the two remaining atoms with no bonded phosphine (Au2 and Au5). The cyclic structure formed by the Au atoms suggests two main types of aurophilic interactions, one between any two neighbouring atoms belonging to the first group and the other between two proximal atoms, an atom from the first and another from the second groups. Any other atomic combinations involve significant interatomic separations and, with the exception of the Au2-Au5 atom pair, do not result in substantial aurophilic interactions.

The strongest aurophilic interaction in the cation occurred between atoms belonging to the first group and the nearest neighbouring atoms from the second group (i.e., in the Au1-Au2 pair and all symmetry equivalents). The respective Mayer Bond Order (MBO) was 0.290 , and Natural Bond Orbital (NBO) decomposition described this interaction as a mixture of numerous orbital delocalisations. These delocalisations occurred mostly into Rydberg orbitals on the acceptor sides. Among all possible NBO donor-acceptor interactions, only the lone-pair $\rightarrow$ Rydberg (LP $\rightarrow$ RY) delocalisations were prevailing. The Au1(LP) $\rightarrow$ Au2(RY) delocalisations occurred from five donor hybrids on Au1, but the principal contribution occurred with the Au1 donor hybrid, primarily of $5 \mathrm{~d}_{\mathrm{xy}}$-character. The total LP $\rightarrow$ RY delocalisation energy was 206.7 kJ $\mathrm{mol}^{-1}$, and the contribution of the $5 \mathrm{~d}_{\mathrm{xy}}$ donor was $154.3 \mathrm{~kJ} \mathrm{~mol}{ }^{-1}$, while its most effective
delocalisation occurred into a hybrid with $84.7 \%$ d-character and $14.4 \%$ p-character on Au2. The reversed Au2(LP) $\rightarrow$ Au1(RY) delocalisations summed even to a higher total energy, although they were generated from three donor lone pairs only. The overall sum of the latter delocalisation energies was $376.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$, with the markedly dominant contribution ( 268.5 kJ $\mathrm{mol}^{-1}$ ) from the $5 \mathrm{~d}_{\mathrm{xy}}$ hybrid donor on Au2.

Figure S1. Simplified structure diagram of the complex cation in 5/5a derived from DFT optimised coordinates. Hydrogen atoms are omitted and only the pivotal carbon atoms from the phenyl rings are shown.

The second strongest aurophilic interaction occurred in the pairs of neighbouring atoms from the first group (i.e., in the Au1-Au4 and Au3-Au6 pairs), with the respective MBO reaching 0.172. Even this interaction was generated mostly by $\operatorname{Au}(\mathrm{LP}) \rightarrow \mathrm{Au}(\mathrm{RY})$ delocalisations, with the $5 \mathrm{~d}_{\mathrm{xy}}$ donor prevailing again, accounting for $44.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$ of the total delocalisation energy ( 80.7 $\mathrm{kJ} \mathrm{mol}{ }^{-1}$ ). The most effective delocalisation of $5 \mathrm{~d}_{\mathrm{xy}}$ was observed into a hybrid with $81.1 \% \mathrm{~d}-$ character, $16.6 \%$ p-character and $2.3 \%$ s-character on the acceptor side. Because the atoms involved in this particular aurophilic interaction are symmetrically equivalent, all donoracceptor interactions occur in equal extents in both donor-acceptor schemes.

The third and weakest aurophilic interaction was observed between Au2 and Au5, with a reported MBO of 0.144 , despite an interatomic separation of $3.942 \AA$. This interaction was primarily generated by $\operatorname{Au}(\mathrm{LP}) \rightarrow \mathrm{Au}(\mathrm{RY})$ delocalisations which used four lone pairs on the donor side. The predominant donor hybrid mostly consisted of $5 \mathrm{~d}_{\mathrm{xy}}$ character, albeit with a significant portion of $5 \mathrm{~d}_{x^{2}-y^{2}}$ mixed in. This particular hybrid accounted for $38.2 \mathrm{~kJ} \mathrm{~mol}^{-1}$ of the overall delocalisation energy ( $43.8 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). This donor hybrid exhibited its most effective delocalisation into an acceptor hybrid of $13.8 \%$ s character, $26.4 \%$ p character and $59.8 \%$ d-
character, while the second most effective delocalisation occurred into an acceptor of $95 \%$ dcharacter. The most important orbital contributions to the first acceptor hybrid were the $6 \mathrm{~d}_{z^{2}}{ }^{2}$, $7 \mathrm{p}_{\mathrm{z}}, 7 \mathrm{~d}_{\mathrm{x}}, 8 \mathrm{p}_{\mathrm{z}}$ and 8 s orbitals, while the $6 \mathrm{~d}_{\mathrm{x}}{ }^{2} \mathrm{y}^{2}$ orbital contributed predominantly to the second hybrid. The acceptor orbitals used to generate aurophilic interactions were already considerably diffuse and thus allowed generation of long-range interaction(s) in the cation of 5 . Since the last aurophilic interactions were generated between symmetrically equivalent atoms, all respective donor-acceptor interactions occurred symmetrically in both donor-acceptor directions.

## Comparison of compounds 5, 6 and 7

The correlation of the computed molar volumes of the cations present in compounds 5, $\mathbf{6}$ and $\mathbf{7}$ (Table S1) with the atomic radii of M2/M5 within their metallic rings suggested that their overall geometry is controlled by factors other than these radii. After optimising the geometry of these cations, we observed that they all became isostructural and adopted the $D_{2}$ symmetry (Figure S2). The largest computed molar volume was determined for $\mathbf{6}$, while the hexagold cation in 5, containing the most voluminous metals, showed the most compact arrangement. The loose correlation between the computed molar volumes and the atomic radii of M2/M5 (Cu: 1.45 $\AA, \mathrm{Ag} 1.65 \AA, \mathrm{Au} 1.74 \AA)^{12}$, suggests that electronic effects of the auxiliary ligands play an important role. The largest molar volume of $\mathbf{6}$ is not only the consequence of more voluminous central ring, but also of the weakest Au-P overlaps present among all cations (Table S1). By contrast, the Au-M overlaps of $\mathbf{5}$ are considerably more effective than those of other cations and coupled with long-range interaction between M2 and M5 (see below), which also explains why $\mathbf{5}$ has the lowest molar volume since such an interaction could even counterbalance the effect of weakened Au-P overlaps, which became the strongest in the $\mathrm{Cu}-\mathrm{Ag}$ complex 7 .

Figure S2. (left) Simplified structure diagram of the complex cations in 5-7 and (right) detailed view of the central six-membered ring.

Table S1. Summary of the DFT computed parameters of the cations in 5-7

${ }^{a}$ Nuclear Independent Chemical Shift value at the Au1-M2-Au3-Au6-M5-Au4 ring centroid.

Although the molar volume of both $\mathbf{6}$ and $\mathbf{7}$ could be decreased by decreasing M2-M5 separations, such a geometry change is prevented by the existing strain within the central ring, as shown by the $\mathrm{Au}-\mathrm{Au}-\mathrm{M}$ (e.g., Au4-Au1-M2) angles. Among the three cations, only in $\mathbf{5}$ does this strain become partly compensated by the direct interaction between M2 and M5. The direct interaction between M2 and M5 allows the most advantageous electron distribution across the central ring of 5, which is also the least antiaromatic ring among the three cations.

All Au-P bonds within the cations were decomposed into concurrent contributions from $P \rightarrow A u$ coordination and $\mathrm{Au} \rightarrow \mathrm{P}$ back-donation. The most effective $\mathrm{P} \rightarrow \mathrm{Au}$ interaction was identified in 5, while the weakest $\mathrm{Au} \rightarrow \mathrm{P}$ back-donation occurred in 7. A more precise bonding description, however, suggested that all Au-P bonds are effected by $3 c 4 e$ hyperbonds, generated between the neighbouring Au and P atoms and the closest ferrocenyl carbon atom (C1/C31/C61/C91) coordinated midway between one Au atom and its neighbouring M. The generation of such hyperbonds accounts for the significant influence of the phosphine moieties on the M atoms, despite substantial $\mathrm{P}-\mathrm{M}$ interatomic separations. Since the $\mathrm{P}, \mathrm{Au}$, and $\mathrm{C}^{\mathrm{Fc}}$ atoms are nearly collinear, any hyperbonds generated between them can stabilise the $M$ atoms through long-range interactions with the phosphine moieties. Together with direct M -Au overlaps, these factors explain the stabilisation of the central rings (Table S2).

Table S2. Delocalisation energies ( $\mathrm{kJ} \mathrm{mol}^{-1}$ ) between the $\mathrm{P}-\mathrm{Au}, \mathrm{P}-\mathrm{M}$ and $\mathrm{Au}-\mathrm{M}$ atom pairs of cations 5-7 ${ }^{a}$

| 5 (Au) | 811.2 | 489.6 | 1300.8 | 28.2 | 661.2 | 208.4 | 352.4 | 560.8 |
| 6 (Ag) | 613.0 | 566.7 | 1179.7 | 28.3 | 557.8 | 215.3 | 271.5 | 486.8 |
| 7 (Cu) | 620.7 | 642.0 | 1262.7 | 18.4 | 537.7 | 165.4 | 287.3 | 452.7 |

[^0]Among the three cations, the overall phosphine to M contributions were the weakest in 7; in conjunction with the least effective direct Au-Cu overlap, these factors explain why this cation has the Cu atoms bonded least stably. These phosphine contributions occurred as lonepair delocalisations into the metallic Rydberg acceptors.

The direct $\mathrm{Au}-\mathrm{M}$ interactions were decomposed into two complementary contributions by NBO-into delocalisations from Au to M and backwards (Table S3). The most effective delocalisation was identified in 5 , namely the delocalisation of M into Au . This delocalisation occurred from three donor lone-pair hybrids on Au , while the most effective was of predominantly $5 \mathrm{~d}_{\mathrm{xy}}$ character, accounting for $268.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ of the total $\mathrm{M} \rightarrow \mathrm{Au}$ delocalisation energy ( $347.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). Although this donor hybrid is delocalised into as many as 20 acceptor orbitals, only three prevailing contributions are detected, with energies of $47.5,38.0$ and 35.4 $\mathrm{kJ} \mathrm{mol}^{-1}$. The most effective delocalisation occurs into a hybrid acceptor with $84 \% \mathrm{p}$-character and is generated by mixing mostly the $6 p_{x}, 6 p_{y}$ and $7 p_{x}$ orbitals. The second acceptor hybrid is of $57.5 \%$ p-character, $21.5 \%$ s-character and $21 \%$ d-character and is generated by mixing $6 p_{x}, 6 p_{y}$ and 8 s . The third hybrid consists of $65.6 \%$ d-character, $21 \%$ d-character and $13.4 \%$ s-character, mixed mostly from $6 \mathrm{~d}_{\mathrm{xy}}$.

Table S3. Delocalisation energies from M into Au and Au into M of 5-7 and their sum ( $\mathrm{kJ} \mathrm{mol}^{-1}$ )

| Cation (M) | $\mathbf{M} \rightarrow \mathbf{A u}$ | $\mathbf{A u} \rightarrow \mathbf{M}$ | $\boldsymbol{\Sigma}_{\text {deloc }}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{5}(\mathrm{Au})$ | 347.1 | 206.7 | 553.8 |
| $\mathbf{6}(\mathrm{Ag})$ | 271.5 | 215.3 | 486.8 |
| $\mathbf{7}(\mathrm{Cu})$ | 287.1 | 165.1 | 452.2 |

In 5, where this type of interaction is the most impaired, the donor hybrid has $97 \% \mathrm{~d}$ character, with a predominant contribution from $4 \mathrm{~d}_{\mathrm{xy}}$. The delocalisation from this hybrid is again the most effective, accounting for $231.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$ of the overall energy ( $271.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). On the acceptor side, however, no terms prevail, and the most effective overlap, with an energy of $27.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$, is achieved by a hybrid with $61.4 \% \mathrm{p}$-character and with contributions from the $6 p_{x}, 7 p_{x}, 8 p_{x}$ orbitals. These results suggest that orbitals involved in this delocalisation become more separated in energy within the heterobimetallic cations, causing a less efficient metalmetal interaction. In the least stable complex 7, the $\mathrm{Au} \rightarrow \mathrm{M}$ delocalisation becomes particularly impaired; the donor hybrid on its Au mostly consists of $5 \mathrm{~d}_{\mathrm{x} y}$, while the most effective acceptor hybrid consists of a mixture of $4 \mathrm{~d}_{x y}, 4 \mathrm{~d}_{z}{ }^{2}$ and 5 s .

## X-RAY CRYSTALLOGRAPHY

Diffraction data were collected on a Bruker Apex II ( $\mathbf{1} \cdot \mathrm{CHCl}_{3}$ ) or a Bruker D8 VENTURE Kappa Duo diffractometer (all other compounds) equipped with a Cryostream Cooler (Oxford Cryosystems), using Mo K $\alpha$ radiation ( $\lambda=0.71073 \AA$ ). The structures were solved using direct methods (SHELXT-2014 ${ }^{13}$ ) and refined using full-matrix least-squares minimisation on $F^{2}$ (SHELXL-2014/201714). Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogens were placed in their theoretical positions and refined as riding atoms with $U_{\text {iso }}(\mathrm{H})$ set to a multiple of $U_{\mathrm{eq}}(\mathrm{C})$ of their bonding carbon atoms. Structure-specific details are provided below.

Because of inefficient packing of the relatively large and irregularly shaped complex cations, the complexes typically contained structural voids, which accommodated the counter anions and disordered solvent molecules. If no reliable structure model could be found for the solvent molecules, their contribution to the overall scattering was eliminated using PLATON SQUEEZE. ${ }^{15}$ This approach was applied to the solvent molecules in $5 \mathbf{5 a} \cdot \mathrm{MeCN} \cdot 4 \mathrm{CH}_{2} \mathrm{Cl}_{2}$, where 748 electrons were removed from the unit cell (space group $P 2_{1} / c, Z=4$ ), matching the expected value ( 760 electrons), and to 1.5 acetonitrile molecule in $6 \cdot 3.5 \mathrm{MeCN} \cdot \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ ( 64 electrons removed, 64 electrons expected; space group $P-1, Z=2$ ). For $9 \cdot \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$, one 1,2 -dichloroethane molecule was refined over two positions, and the other was treated as diffuse scattering. In total, 214 electrons were eliminated from the unit cell $(C 2 / c, Z=4)$, also corresponding to the expected value ( 200 electrons).

The data on the crystals of $\mathbf{1 0} \cdot 1.5 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ had to be collected at 230 K because the crystals disintegrated upon cooling below this temperature, most likely due to phase transition. Even in this case, the solvent molecules were treated by PLATON SQUEEZE ( 280 electrons removed, 252 electrons expected). In addition, one phenyl ring and one fluorine atom had to be refined over two positions. For 1.CHCl 3 , PLATON SQUEEZE was used to eliminate diffuse electron density near the solvent molecule (likely another orientation of the solvent molecule; 39 electrons per the unit cell). Lastly, the crystal of $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$ was a two-component non-merohedral twin. The twin matrix and the ratio of the two contributing domains were [100;0-1 0;-0.735 0-1] and 88:12, respectively.

Crystallographic data and refinement parameters are outlined in Table S4. The geometric data and structural diagrams were obtained using the PLATON program. ${ }^{16}$ Complete crystallographic data were deposited at the Cambridge Crystallographic Data Centre and are available from www.ccdc.cam.ac.uk/data_request/cif, by email at data_request@ccdc.cam.ac.uk or by contacting The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033. The deposition numbers are outlined in Table S4.

## Crystal structure of $1 \cdot \mathrm{CHCl}_{3}$

The compound crystallizes in the monoclinic space group $P 2_{1} / n$ as a monochloroform solvate. A view of the molecular structure is shown in Figure S3, and the geometric parameters are outlined in Table S5. Both structurally independent gold atoms in $\mathbf{1}$ are linearly coordinated, and their distance excludes any intramolecular aurophilic interaction (Au1 $\cdots \mathrm{Au} 2=4.2516(3) \AA$ ). The $\mathrm{Au}-\mathrm{C}$ and $\mathrm{Au}-\mathrm{P}$ distances are similar to those in $\left[\mathrm{FcAu}\left(\mathrm{PPh}_{3}\right)\right] .{ }^{17}$ The ferrocene units are negligibly tilted and adopt an approximately $1,2^{\prime}$ conformation (ideal value: $72^{\circ}$ ).

Figure S3. PLATON plot of the complex molecule in the structure of $\mathbf{1} \cdot \mathrm{CHCl}_{3}$ showing displacement ellipsoids at the $30 \%$ probability level.

Table S5. Selected geometric parameters for $\mathbf{1} \cdot \mathrm{CHCl}_{3}\left(\right.$ in $\AA$ and deg) ${ }^{a}$

| Au1-C1 | $2.033(4)$ | Au2-C31 | $2.040(4)$ |
| :--- | :--- | :--- | :--- |
| Au1-P2 | $2.290(1)$ | Au2-P1 | $2.278(1)$ |
| C1-Au1-P1 | $177.9(1)$ | C31-Au2-P1 | $179.4(1)$ |
| Fe1-C(1-10) | $2.028(4)-2.107(4)$ | Fe2-C(31-40) | $2.033(4)-2.074(4)$ |
| tilt(Fe1) | $2.3(2)$ | tilt(Fe2) | $1.2(2)$ |
| $\tau(\mathrm{Fe} 1)$ | $-83.9(3)$ | $\tau(\mathrm{Fe} 2)$ | $-84.8(3)$ |

${ }^{a}$ Definitions: tilt is the dihedral angle of the least-squares cyclopentadienyl planes and $\tau$ stands for the torsion angle C1-Cg1-Cg2-C6 for Fe 1 (C31-Cg3-Cg4-C36 for Fe 2 ), where Cg denotes the respective cyclopentadienyl ring centroid.

## Crystal structure of $\mathbf{2 \cdot 2 . 5} \mathrm{C}_{2} \mathbf{H}_{4} \mathrm{Cl}_{2}$

The structure of compound $\mathbf{2} \cdot 2.5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ and a view of the tetragold core in its complex cation are shown in Figures S4 and S5, respectively. Relevant structural parameters are presented in Table S6.

Figure S4. A complete structural diagram for $\mathbf{2} \cdot 2 \cdot 5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ with $30 \%$ displacement ellipsoids.

The geometry of the complex cation is generally similar to that of a tetrafluoroborate salt reported previously. ${ }^{18}$ Unlike this reference compound, however, the cation in 2 lacks any imposed symmetry. Formally, the cation can be described as metalloligand $\mathbf{1}$ with two additional $\mathrm{LAu}^{+}$fragments ( $\mathrm{L}=\mathrm{FcPPh}_{2}$ ), forming a tetragold complex cation. This notion is consistent with the nearly linear C1-Au1-P2 (173.26(8) $)^{\circ}$ ) and C31-Au2-P1 (171.88(9) ${ }^{\circ}$ ) angles and more bent C1-Au3-P3 (161.90(0) $)$ and C31-Au4-P4 (160.40(9) ${ }^{\circ}$ ) angles. The Au1 $\cdots$ Au2 (3.2201(6) Å) and, mainly, the $\mathrm{Au} 3 \cdots \mathrm{Au} 4\left(4.3624(6) \AA\right.$ ) distance in $2 \cdot 2.5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ are significantly longer than the $\mathrm{Au} \cdots \mathrm{Au}$ distances within the geminally diaurated fragments ( $\mathrm{Au} 1 \cdots \mathrm{Au} 32.7813(6) \AA, \mathrm{Au} 2 \cdots \mathrm{Au} 4$ 2.7572(5); cf. 2.768(3) $\AA$ in $\left[\mathrm{Fc}\left\{\mathrm{Au}_{\left.\left.\left.\left(\mathrm{PPh}_{3}\right)\right\}_{2}\right]\left[\mathrm{BF}_{4}\right]^{19}\right) \text {. The corresponding Au-C distances (Au1-C1 }}\right.\right.$ $2.134(3) \AA$, Au3-C1 2.136(3) $\AA$, Au2-C31 2.131(4) $\AA$, and Au3 $\cdots$ C31 2.136(3) $\AA$ ) are identical
within the margins of experimental error, and all $\left\{\mathrm{AuC}_{2}\right\}$ fragments are oriented perpendicularly to the planes of their parent cyclopentadienyl rings (cf. \{Au1,Au3,C1\} vs. $\mathrm{C}(1-5) 88.0(2)^{\circ}$, $\{\mathrm{Au} 2, \mathrm{Au} 4, \mathrm{C} 31\}$ vs. $\left.\mathrm{C}(31-35) 89.3(2)^{\circ}\right)$. The ferrocene units are tilted by $10.3(2)^{\circ}(\mathrm{Fe} 1)$ and $9.5(2)^{\circ}(\mathrm{Fe} 2)$, which is also reflected by the larger variation in $\mathrm{Fe}-\mathrm{C}$ bonds (compare the Fe1-C(110) $2.037(3)-2.098(3) \AA$ and $\mathrm{Fe} 2-\mathrm{C}(31-40) 2.035(4)-2.094(3) \AA$ distances in the aurated ferrocene units with the Fe3-C(61-10) 2.031(3)-2.056(4) $\AA$ and $\operatorname{Fe} 4-C(91-100)$ 2.036(3)$2.054(4) \AA$ distances in the terminal phosphine ligands). The Au-P bonds of the aurated ferrocene ligand (Au1-P2 2.291(1) Å and Au2-P1 2.284(1) $\AA$ ) are slightly elongated with respect to the Au-P distances of the non-aurated ligands (Au3-P3 2.269(1) Å, Au4-P4 2.262(1) Å).

Figure S5. Simplified view of the tetragold core in the complex cation of $\mathbf{2} \cdot 2 \cdot 5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$. All hydrogens and phenyl ring carbons except for pivotal ones are omitted.

## Crystal structure of $\mathbf{3 . 2} \mathbf{C}_{6} \mathbf{H}_{5} \mathrm{~F}$

The complex cation in the structure of $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$ is structurally analogous to that of $\mathbf{2} \cdot 2 \cdot 5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ discussed above, bearing two tricyclohexylphosphine ( $\mathrm{PCy}_{3}$ ) molecules as terminal ligands (Figure S6 and S7, parameters in Table S7). Replacing $\mathrm{FcPPh}_{2}$ with the bulkier $\mathrm{PCy}_{3}$ ligands increases the twisting of the U-shaped array of the four gold atom, as illustrated by the torsion angles Au3-Au1-Au2-Au4 -8.37(2) ${ }^{\circ}$ in $\mathbf{2} \cdot 2.5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$, and $14.76(2)^{\circ}$ in $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$. Accordingly, the variation in the $\mathrm{Au}-\mathrm{C}$ distances of $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$ is larger (the outer gold atoms Au 2 and Au 4 form longer Au-C bonds than the internal ones, Au1 and Au3), and the Au3-P3 and Au4-P4 bonds are elongated with respect to those in $\mathbf{2} \cdot 2 \cdot 5 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$.

Figure S6. Complete structural diagram of $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$ with displacement ellipsoids scaled to the 30\% probability level

Figure S7. Simplified view of the tetragold core in the complex cation of $\mathbf{3} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$. All hydrogens and phenyl ring carbons except for pivotal ones are omitted.

Table S7. Selected distances and angles of $5 \cdot 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~F}$ (in Å and deg)

| Au1 $\cdots \mathrm{Au} 3$ | $2.782(1)$ | Au2 $\cdots \mathrm{Au} 4$ | $2.771(1)$ |
| :--- | :--- | :--- | :--- |
| Au1-C1 | $2.122(6)$ | Au2-C31 | $2.124(6)$ |

| $\varphi$ | $11.64(1)$ | $7.11(1)$ | $\tau(\mathrm{Fe} 4)$ | $68.8(4)$ | $-65.6(2)$ |

${ }^{a}$ Tilt and $\tau$ are defined as for $\mathbf{1} \cdot \mathrm{CHCl}_{3} ; \varphi$ is the angle between the (Au1 $\left.\cdots \mathrm{Au} 3\right) /(\mathrm{Au} 4 \cdots \mathrm{Au} 6)$ lines.

## Crystal structures of $\mathbf{8} \cdot \mathbf{3} \mathrm{CH}_{\mathbf{2}} \mathrm{Cl}_{2}$ and $\mathbf{9 \cdot 2} \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$

The $\mathrm{Cu}-\mathrm{Au}$ complexes $\left[\left(\mu_{4}-\mathrm{O}\right)\left\{\left(\mathrm{Ph}_{2} \mathrm{PfcAu}\right)_{2} \mathrm{Cu}_{2}\right\}_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}$ (8) and $\left[(\mu-\mathrm{Cl})\left\{\left(\mathrm{Ph}_{2} \mathrm{PfcAu}_{2} \mathrm{Cu}_{2}\right\}_{2}\right]\left[\mathrm{BF}_{4}\right]\right.$ (9) are closely structurally related; therefore, their structures will be discussed jointly. In fact, the compounds differ only in their bridging ligand, whose nature dictates whether it will act as a bridge within one dicuprated metalloligand 1 (viz., $\left\{\mathrm{Ph}_{2} \mathrm{PfcAu}_{2} \mathrm{Cu}_{2}\right.$ ) or interconnect two such moieties. Structures of the complex cations are shown in Figures S9 and S10; selected geometric data are outlined in Table S9.

Figure S9. Full (left) and partial (right) structure diagram for the cation in $\mathbf{8} \cdot 3 \mathrm{CH}_{2} \mathrm{Cl}_{2}$.

Figure S10. PLATON plot of the complex cation in the structure of $9 \cdot 2 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ showing displacement ellipsoids at the 30\% probability level.

The complex cation in $\mathbf{9}$ consists of two equivalent parts, which are are mutually tilted, as illustrated by the dihedral angles of the $\{\mathrm{Au} 1, \mathrm{Cu} 1, \mathrm{C} 1\}$ and $\{\mathrm{Au} 2, \mathrm{Cu} 2, \mathrm{C} 31\}$ planes $\left(72.1(2)^{\circ}\right)$ or by the angle between the metalated cyclopentadienyl planes $\mathrm{C}(1-5)$ and $\mathrm{C}(31-35)$ (74.2(3) ${ }^{\circ}$ ). Compound $\mathbf{9}$ has longer Au-C bonds (by 0.06-0.07 $\AA$ ) and narrower C-Au-P angles (by 3-4 ${ }^{\circ}$ ) than the parent $\mathbf{1}$, in line with the presence of an additional metal atom $(\mathrm{Cu})$ bonding to the aurated cyclopentadienyl carbon (C1/C31) in 9. Similarly to the structure of $\mathbf{2}$ and $\mathbf{3}$, the $\{\mathrm{Au} 1, \mathrm{Cu} 1, \mathrm{C} 1\}$ and $\{\mathrm{Au} 2, \mathrm{Cu} 2, \mathrm{C} 31\}$ planes in $\mathbf{9}$ are oriented nearly perpendicularly to the plane of their parent cyclopentadienyl rings ( $\mathrm{C}\left(1-5\right.$ ) and $\mathrm{C}(31-35)$; the respective dihedral angles are $78.4(2)^{\circ}$ and $\left.80.2(3)^{\circ}\right)$. The $\mathrm{Au}-\mathrm{Cu}$ distances $(\approx 2.58 \AA$ ) are shorter than the sum of the respective covalent radii $(2.68 \AA)^{[20]}$ and match the $\mathrm{Au}-\mathrm{Cu}$ separation observed in polymeric complexes $\left[\left\{\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{2} \mathrm{Au}\right\}\{\mathrm{Cu}(\mathrm{MeCN})\}\right]_{n}$ featuring bridging pentafluorophenyl ligands ( 2.57 and $2.59 \AA$ Å). ${ }^{[21]}$ The ferrocene cyclopentadienyls are tilted by approximately $10-12^{\circ}$ and mutually rotated into an approximately $1,2^{\prime}$ conformation.

As stated already above, compound 8 contains two $\left\{\mathrm{Ph}_{2} \mathrm{PfcAg}_{2} \mathrm{Cu}_{2}\right.$ units connected by a quadruply bridging oxide ligand. The geometry of the two structurally independent $\left\{\mathrm{Ph}_{2} \mathrm{PfcAg}\right\}_{2} \mathrm{Cu}_{2}$ moieties is similar to that of $\mathbf{9}$ (see Table S8), but the distances of the $\mathrm{Cu}(\mathrm{I})$ ions towards the bridging ligand are shorter ( $\mathrm{Cu}-\mathrm{O}<\mathrm{Cu}-\mathrm{Cl}$ ), which brings the two $\left\{\mathrm{Ph}_{2} \mathrm{PfcAg}_{2} \mathrm{Cu}_{2}\right.$ fragments closer, thereby distorting the sterically crowded environment of the bridging oxygen atom from ideally tetrahedral (Cu1-01-Cu4 117.67(9) ${ }^{\circ}$, Cu2-01-Cu3 129.1(1) ${ }^{\circ}$, Cu2-01-Cu4 $109.84(8)^{\circ}$, and $\left.\mathrm{Cu} 3-01-\mathrm{Cu} 484.20(8)^{\circ}\right)$.

Table S9. Selected distances and angles for $\mathbf{8} \cdot 3 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathbf{9} \cdot 2 \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}$ (in $\AA$ and deg)

${ }^{a}$ Given are the analogous parameters for the "second", chemically equivalent half of the complex cation.

## Crystal structure of $\mathbf{1 0} \cdot \mathbf{1 . 5} \mathbf{C H}_{\mathbf{2}} \mathrm{Cl}_{2}$

The cation in the structure of $\mathbf{1 0} \cdot 1.5 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ resides over the crystallographic centre. As a result, only half of this cation is structurally independent (Figure S11, parameters in Table S10). The structure of the cation can be regarded as metalloligand 1 capped by two \{Cu(MeCN)\}+ fragments on both sides of the central $\left\{\mathrm{Au}_{2} \mathrm{C}_{2} \mathrm{P}_{2}\right\}$ ring: the pairs of $\mathrm{Au} 1, \mathrm{C} 1$ and P 1 atoms that form a six-membered ring are coplanar within approximately $0.03 \AA$, and the $\mathrm{Cu} 1 / \mathrm{Cu} 1$ ' atom are displaced $1.5164(4) \AA$ above and below the mean ring plane (see alternative view in Figure S11).

Figure S11. Complete diagram (left) and simplified side view (right) of the complex cation in the structure of $\mathbf{1 0} \cdot 1.5 \mathrm{CH}_{2} \mathrm{Cl}_{2}$. Only one position of the disordered phenyl ring $\mathrm{C}(17-22)$ is shown for clarity. The prime-labelled atoms are generated by crystallographic inversion.

Table S10. Selected distances and angles of $\mathbf{1 0} \cdot 1 \cdot 5 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (in $\AA$ and deg)

| Au1 $\cdots$ Au1' $^{\prime}$ | $4.1035(5)$ | tilt | $11.2(2)$ |
| Cu1 $\cdots$ Cu1' $^{\prime}$ | $3.8101(6)$ | $\tau$ | $-62.5(2)$ |

The central $\left\{\mathrm{Au}_{2} \mathrm{Cu}_{2}\right\}$ ring is compressed along the $\mathrm{Cu} \cdots \mathrm{Cu}$ diagonal, as evidenced by the Au1 $\cdots \mathrm{Au} 1^{\prime}$ and Cu1 $\cdots \mathrm{Cu} 1^{\prime}$ distances and the interring angle ( 86 and $94^{\circ}$ ). The copper(I) ions are further coordinated by terminal acetonitrile ligands (Cu1-N1 1.888(3) Å, C31-N1 1.123(6) Å), which extend away from the centre of the molecule (the angle between the plane of the $\left\{\mathrm{Au}_{2} \mathrm{C}_{2} \mathrm{P}_{2}\right\}$ ring and the $\mathrm{C} 31-\mathrm{N} 1$ bond is $\left.62.5(3)^{\circ}\right)$. Otherwise, the geometric parameters of the $\left\{\left(\mathrm{Ph}_{2} \mathrm{PfcAu}\right)_{2} \mathrm{Cu}_{2}\right\}$ motif in $\mathbf{1 0}$ are generally similar to those of $\mathbf{8}$ and $\mathbf{9}$. The $\{\mathrm{Au} 1, \mathrm{Cu} 1, \mathrm{C} 1\}$ plane is oriented nearly perpendicularly to the cyclopentadienyl plane involving C1 (dihedral angle $\left.82.3(2)^{\circ}\right)$, and the ferrocene cyclopentadienyls are tilted $\left(11^{\circ}\right)$ and mutually rotated by $\approx 63^{\circ}$.

## COPIES OF THE NMR AND MS SPECTRA

(Note: residual solvent signals in the NMR spectra are denoted by an asterisk.)

Figure S12. ${ }^{1} \mathrm{H}$ NMR spectrum $\left(399.95 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ of $\mathbf{1}$.

Figure S13. ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum $\left(100.58 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ of $\mathbf{1}$.
