## Syntheses of the alkylation agents

The $N$-(2-bromoethyl)-, $N$-(3-bromopropyl)- and $N$-(4-bromobutyl)-phthalimides were prepared by reaction of $\alpha, \omega$ dibromoalkane in excess (5 equiv.) with potassium phthalimide in DMF at room (ethyl derivative) or elevated ( $50{ }^{\circ} \mathrm{C}$, propyl and butyl derivatives) temperatures. Volatiles were evaporated on vacuum rotary evaporator and the residues were taken up in a $\mathrm{H}_{2} \mathrm{O} / \mathrm{EtOAc}$ mixture. Products were isolated by evaporation of the organic phase and purified by crystallization from boiling EtOH. Less soluble bis(phthalimido)alkane by-products [e.g. 1,4-bis(phthalimido)butane, see Figure S2] were removed by filtration of the hot EtOH solution and the products - the alkylation agents crystallized from the cooled solution on standing.

## Characterization of the prepared compounds

The NMR spectra were acquired at $25^{\circ} \mathrm{C}$.

## 4,11-Dibenzyl-1,8-bis(2-phthalimidoethyl)-1,4,8,11-tetraazacyclotetradecane (1a)

Elem. anal.: Found (calcd. for 1a, $\mathrm{C}_{44} \mathrm{H}_{50} \mathrm{~N}_{6} \mathrm{O}_{4}, M_{\mathrm{r}}=726.92$ ). C 72.63 (72.70); H 6.70 (6.93); N 11.26 (11.56) \%.

## Determination of crystal structures by X-ray diffraction

The selected crystals of $\mathbf{1 a}, \mathbf{1 b}$ and $\mathbf{3 a}$ were mounted on a glass fibre in a random orientation and the diffraction data were collected at 150 K (Cryostream Cooler, Oxford Cryosystem) by Nonius KappaCCD diffractometer equipped with a Bruker APEX-II CCD detector using monochromatized $\mathrm{Mo}-\mathrm{K}_{\alpha}$ radiation ( $\lambda=0.71073 \AA$ ). Data of other crystals were acquired at 120 K (Cryostream Cooler, Oxford Cryosystem) with Bruker D8 VENTURE Kappa Duo PHOTON100 diffractometer with an $\mathrm{I} \mu \mathrm{S}$ micro-focus sealed tube using monochromatized $\mathrm{Mo}-\mathrm{K}_{\alpha}$ radiation $\left\{\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} \mathbf{1}\right)\right]\left(\mathrm{ClO}_{4}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O},[\mathrm{Cu}(\mathbf{L 1})]\left(\mathrm{ClO}_{4}\right)_{2},\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L 2}\right)\right]\left(\mathrm{ClO}_{4}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O},[\mathrm{Cu}(\mathbf{L 2})]\left(\mathrm{ClO}_{4}\right)_{2},[\mathrm{Cu}(\mathbf{L 3})]\left(\mathrm{ClO}_{4}\right)_{2}\right\}$ or with $\mathrm{Cu}-\mathrm{K}_{\alpha}$ radiation $(\lambda=1.54178 \AA)\left\{1,4\right.$-bis(phthalimido)butane, $\left(\mathrm{H}_{2} \mathbf{2 b}\right)\left(\mathrm{C}_{8} \mathrm{H}_{5} \mathrm{~N}_{2} \mathrm{O}_{2}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}, \quad\left(\mathrm{H}_{6} \mathbf{L} \mathbf{L}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, $\left.\left(\mathrm{H}_{6} \mathbf{L 2}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O},\left\{(\mu-\mathrm{Cl})\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} 2\right)\right]_{2}\right\}\left(\mathrm{ClO}_{4}\right)_{7} \cdot 3 \mathrm{H}_{2} \mathrm{O}\right\}$.
Data were analysed using the SAINT software package (Bruker AXS Inc.). Data were corrected for absorption effects using the multi-scan method (SADABS). ${ }^{[1]}$ All structures were solved by direct methods (SHELXT2014) ${ }^{[2]}$ and refined using full-matrix least-squares techniques (SHELXL2017). ${ }^{[3]}$

In general, all non-hydrogen atoms were refined anisotropically. Hydrogen atoms were usually localized in difference density map. However, hydrogen atoms bound to the carbon atoms were placed in theoretical positions using $U_{\mathrm{eq}}(\mathrm{H})=$ $1.2 U_{\text {eq }}(\mathrm{C})$ to keep a number of parameters low and only hydrogen atoms bound to the heteroatoms $(\mathrm{O}, \mathrm{N})$ were usually refined. For detailed description of crystal structures of the organic compounds see ESI (Figures S2-S10 and accompanying text).

The crystal structure of $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} \mathbf{1}\right)\right]\left(\mathrm{ClO}_{4}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ poses centre of symmetry and, thus, one half of the formula unit form the structurally independent part. In the structure of $[\mathrm{Cu}(\mathbf{L 1})]\left(\mathrm{ClO}_{4}\right)_{2}$, the complex molecule also poses centre of symmetry but the molecule was found disordered over two positions (Figure S11). Both disordered parts share central $\mathrm{Cu}($ II $)$ ion and pivot carbon atom of the trifluoromethyl group; fluorine atoms were refined disordered over two positions. The perchlorate anion was also best refined with all oxygen atoms disordered over two positions. Despite a number of experiments to obtain crystals of kinetic isomer of complexation in the $\mathrm{Cu}^{2+}-\mathbf{L} \mathbf{2}$ system, only clusters/druses of very small crystals with composition $\left\{(\mu-\mathrm{Cl})\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} 2\right)\right]_{2}\right\}\left(\mathrm{ClO}_{4}\right)_{7} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ were obtained with need to disassemble them mechanically to obtain measureable single-crystals. The crystals were only poorly diffracting. For the best crystal whose data are presented in this manuscript, a total of 2569 frames were collected with the total exposure time was 19.91 hours, and only 4620 of 13563 unique reflections had intensity $I>2 \sigma(I)$, see Figure S1. In the crystal structure, whole formula unit forms the structurally independent part. One terminal trifluoromethyl group was best refined staggered in two disordered positions. Several perchlorate anions were also refined with oxygen atoms disordered over two positions and sharing the same chlorine atom. Two perchlorate anions were modelled with even chlorine atom disordered over two positions.

Figure S 1 . Graphical representation of diffraction data quality of single-crystal of $\left.\left\{(\mu-\mathrm{Cl})\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} 2\right)\right]_{2}\right\}\left(\mathrm{ClO}_{4}\right)\right)^{\prime} \cdot 3 \mathrm{H}_{2} \mathrm{O}$.

In the crystal structure of $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathbf{L} \mathbf{2}\right)\right]\left(\mathrm{ClO}_{4}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, the structurally independent part is formed by whole formula unit. One of perchlorate anions was best refined disordered over two positions sharing one of the oxygen atoms. In the crystal structure of $[\mathrm{Cu}(\mathbf{L 2})]\left(\mathrm{ClO}_{4}\right)_{2}$, two complex molecules and four perchlorate anions form the structurally independent unit. A sidearm of one of the complex molecules was found to be partly disordered over two positions, and oxygen atoms of three perchlorate anions were best refined disordered in two positions (Figure 12). Both independent complex molecules have very similar geometry (Figure S13). In the crystal structure of $[\mathrm{Cu}(\mathbf{L} 3)]\left(\mathrm{ClO}_{4}\right)_{2}$, a formula unit forms the structurally independent part. Oxygen atoms of the perchlorate anions were found to be disordered over two positions and terminal trifluoromethyl groups were refined staggered in two positions.
All the data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-2203686-2203698. For overview of experimental crystallographic data of organic compounds see Table S1, and those of the complexes are outlined in Table S2.

## Experimental crystallographic data of the reported crystal structures

Overview of experimental crystallographic data of organic compounds (ligands and intermediates) is given in Table S1 and data of the complexes are outlined in Table S2.

## Description of crystal structures of organic compounds

All crystal structures of the organic compounds posse a centre of symmetry and an independent part is formed by one half of the formula unit. Some disorder was found only in the crystal structure of $\left(\mathrm{H}_{6} \mathbf{L 1}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ where the trifluoroethyl group was best refined staggered in two positions with relative occupancy $60: 40 \%$, and a water molecule of crystallization was found disordered in two close positions (71:29\%).

## Crystal structure of $\mathbf{1 , 4}$-bis(phthalimido)butane

1,4-bis(phthalimido)butane was isolated as poorly soluble by-product in preparation of $N$-(4-bromobutyl)phthalimide.

Figure S2. Molecular structure of 1,4-bis(phthalimido)butane found in its crystal structure. Only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

## Crystal structures of 1a and 1b

Molecules of both compounds adopt centrosymmetric structure with ( $3,4,3,4$ )-B conformation of the macrocyclic backbone. ${ }^{[4,5]}$ In molecule of 1a (Figure S3), the phenyl and phthalimide moieties are roughly parallel (mutual angle $15.3^{\circ}$ ) and oriented in such a way that one carbonyl group ( $\mathrm{C} 18=\mathrm{O} 18$ ) of phthalimide moiety is placed above a centroid of the phenyl group $\left[d\left(\mathrm{Q}_{\mathrm{Ph}} \cdots \mathrm{C} 18\right)=3.79 \AA, d\left(\mathrm{Q}_{\mathrm{Ph}} \cdots \mathrm{O} 18\right)=3.59 \AA, \mathrm{Q}_{\mathrm{Ph}}\right.$ is the centroid of the phenyl ring $]$. The second carbonyl group (C11, O11) is kept above phthalimido benzene ring of the neighbouring molecule at even slightly shorter distance $\left[d\left(\mathrm{Q}_{\text {phth }}{ }^{\# \ldots \mathrm{C} 11)}=3.52 \AA, d\left(\mathrm{Q}_{\text {phth }}{ }^{\#} \ldots \mathrm{O} 11\right)=3.48 \AA, \mathrm{Q}_{\text {phth }}{ }^{\#}\right.\right.$ is a centroid of the benzene ring of phthalimide group from the neighbouring molecule]. The interactions discussed above stabilize a whole crystal packing (Figure S4).

Figure S3. Molecular structure of 1a found in its crystal structure. Hydrogen atoms are omitted for clarity. Only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

Figure S4. Carbonyl- $\pi$ stacking interactions found in the crystal structure of $\mathbf{1 a}$. Hydrogen atoms are omitted for clarity. Intramolecular contacts are shown in light green, intermolecular contacts in light blue colour.

In the structure of 1b (Figure S5), no significant intramolecular stacking interactions were found. In the crystal packing, imide nitrogen atoms caps the phenyl ring of benzyl group of the neighbouring molecule and forms a weak n $\pi$ interaction $\left[d\left(\mathrm{Q}_{\mathrm{Ph}}{ }^{\#} \ldots \mathrm{~N} 11\right)=3.82 \AA, \mathrm{Q}_{\mathrm{Ph}}{ }^{\#}\right.$ is a centroid of the phenyl ring of the neighbouring molecule, Figure S 6$]$.

Figure S5. Molecular structure of $\mathbf{1 b}$ found in its crystal structure. Hydrogen atoms are omitted for clarity. Only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

Figure S6. Lone pair- $\pi$ stacking interactions found in the crystal structure of $\mathbf{1 b}$ (light blue lines) Hydrogen atoms are omitted for clarity.

## Crystal structure of $\left(\mathrm{H}_{2} 2 \mathrm{~b}\right)\left(\mathrm{C}_{8} \mathrm{H}_{5} \mathrm{~N}_{2} \mathrm{O}_{2}\right)_{2} \cdot \mathbf{2} \mathrm{H}_{2} \mathrm{O}$

In the crystal structure of $\left(\mathrm{H}_{2} \mathbf{2 b}\right)\left(\mathrm{C}_{8} \mathrm{H}_{5} \mathrm{~N}_{2} \mathrm{O}_{2}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, the macrocyclic unit adopt centrosymmetric (3,4,3,4)-B conformation. ${ }^{[4,5]}$ The primary amino groups of the 3 -aminopropyl moiety are protonated, and their space orientation is stabilized by strong hydrogen bonds to the benzyl-bearing macrocycle nitrogen atom, an oxygen atom of phthalhydrazide( $1^{-}$) anion and a water molecule of crystallization (Figure S7). The observed intramolecular hydrogen bond between the pendant arm and the macrocycle amino group is a common motive, whereas, usually, the protonbearing moiety is the macrocycle amino group. Here, the rare example of proton attached to the pendant arm and the macrocycle amino group serving as an acceptor of the hydrogen bond was observed. Well-defined intermolecular hydrogen bond network form tight packing which is responsible for the low solubility to the compound.

Figure S7. Selected part of the $\left(\mathrm{H}_{2} \mathbf{2 b}\right)\left(\mathrm{C}_{8} \mathrm{H}_{5} \mathrm{~N}_{2} \mathrm{O}_{2}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ crystal structure. Carbon-bound hydrogen atoms are omitted for clarity. Hydrogen bonds are shown in turquoise colour. Only atoms belonging to the structurally independent half of the centrosymmetric structure are labelled.

## Crystal structure of 3a

The crystal structure of $\mathbf{3 a}$ revealed presence of centrosymmetric molecule in ( $3,4,3,4$ )-B conformation of the macrocyclic backbone (Figure S8). ${ }^{[4,5]}$ Trifluoroacetamide group is turned to allow formation of medium-strong intramolecular hydrogen bonds between the amide nitrogen atoms and the benzyl-bearing nitrogen atoms of the macrocycle $[d(\mathrm{~N} 10 \cdots \mathrm{~N} 4)=3.27 \AA]$. Similarly to the previous structure, it is rare example of hydrogen bond where the macrocycle amino group serves as the hydrogen atom acceptor.

Figure S8. Molecular structure of 3a found in its crystal structure. Carbon-bound hydrogen atoms are omitted for clarity. Intramolecular hydrogen bonds are shown in turquoise colour. Only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

## Crystal structures of L1 and L2

The ligands $\mathbf{L} 1$ and $\mathbf{L} \mathbf{2}$ were isolated as hydrochloride salts after co-evaporation from their solution in aq. HCl , and their single-crystals were prepared from diluted aq. HCl solution on diffusion of acetone. Obtained hydrochlorides were structurally characterized (Figures S9 and S10). In the crystal structures of both compounds, all amino groups are protonated, giving analogous formulas of the solid materials, $\left(\mathrm{H}_{6} \mathbf{L} \mathbf{1}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and $\left(\mathrm{H}_{6} \mathbf{L 2}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. In both cases, the macrocycles adopt conformation ( $3,4,3,4$ )-A with protonated amino groups located in corners of the rectangle which is the most common conformation for the fully protonated cyclam skeleton as it minimizes electrostatic repulsive forces between the protonated ring amino groups. ${ }^{[4,5]}$

Figure S9. Molecular structure of $\left(\mathrm{H}_{6} \mathbf{L} \mathbf{1}\right)^{6+}$ cation found in the crystal structure of $\left(\mathrm{H}_{6} \mathbf{L 1}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Carbon-bound hydrogen atoms are omitted for clarity. Only fluorine atoms of disordered trifluoromethyl group with the higher occupancy are shown, and only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

Figure S10. Molecular structure of $\left(\mathrm{H}_{6} \mathbf{L 2}\right)^{6+}$ cation found in the crystal structure of $\left(\mathrm{H}_{6} \mathbf{L 2}\right) \mathrm{Cl}_{6} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Carbon-bound hydrogen atoms are omitted for clarity. Only atoms belonging to the structurally independent half of the centrosymmetric molecule are labelled.

## Disorders found in the crystal structures of the $\mathbf{C u}(\mathrm{II})$ complexes

## Disorder in the crystal structure of $[\mathrm{Cu}(\mathrm{L} 1)]\left(\mathrm{ClO}_{4}\right)_{2}$

Figure S 11 . Molecular structure of the $[\mathrm{Cu}(\mathbf{L} \mathbf{1})]^{2+}$ cation found in the crystal structure of $[\mathrm{Cu}(\mathbf{L 1})]\left(\mathrm{ClO}_{4}\right)_{2}$ showing complex cation disorder. Disordered molecule possess centre of symmetry and two molecular positions share the central $\mathrm{Cu}(\mathrm{II})$ ion (Cu1) and the pivot carbon atom (C12) of the trifluoroethyl group. Hydrogen atoms are omitted for clarity, and only selected atoms are labelled.

Table S3. Selected geometric parameters found in the crystal structure of $[\mathbf{C u}(\mathbf{L} \mathbf{1})]\left(\mathrm{ClO}_{4}\right)_{2}$. Donor atoms numbering rises from numbering of the cyclam ring - nitrogen atoms $\mathrm{N} 1, \mathrm{~N} 4, \mathrm{~N} 8$ and N 11 . The axial donors are labelled Dax1 and Dax2, respectively.

## Determination of protonation sites and protonation constants of the ligands in $\mathrm{D}_{\mathbf{2}} \mathrm{O}$

Protonation sites and protonation constants of $\mathbf{L} 1$ and $\mathbf{L} 2$ were determined by following ${ }^{1} \mathrm{H}$ and ${ }^{19}$ F NMR chemical shifts in dependence on " pH " in the range $2-12$ (" pH " means uncorrected reading of the glass combined electrode calibrated using standard buffers in water). Samples of the ligands were dissolved in $\mathrm{D}_{2} \mathrm{O}(450 \mu \mathrm{l})$, and " pH " was adjusted by careful addition of diluted DCl or NaOD in $\mathrm{D}_{2} \mathrm{O}$. In alkaline solution with " pH " $>10$, the ligand $\mathbf{L} 1$ slowly precipitates. Overall protonation constants defined as $\beta_{n}=\left[\mathrm{H}_{n} \mathrm{~L}^{n+}\right] /\left\{[\mathrm{L}] \cdot\left[\mathrm{H}^{+}\right]^{n}\right\}$ were calculated using OPIUM program package. ${ }^{[6]}$ Consecutive protonation constants are defined as $K\left(\mathrm{H}_{n} \mathrm{~L}^{n+}\right)=\left[\mathrm{H}_{n} \mathrm{~L}^{n+}\right] /\left\{\left[\mathrm{H}_{n-1} \mathrm{~L}^{(n-1)+}\right] \cdot\left[\mathrm{H}^{+}\right]\right\}$, and are related to the overall protonation constants by $\log K\left(\mathrm{H}_{n} \mathrm{~L}^{n+}\right)=\log \beta_{n}-\log \beta_{n-1}$. For conversion to $\mathrm{p} K_{\mathrm{A}}$ values, $\log K\left(\mathrm{H}_{n} \mathrm{~L}^{n+}\right)=\mathrm{p} K_{\mathrm{A}}\left(\mathrm{H}_{n} \mathrm{~L}^{n+}\right)$.
In ${ }^{1} \mathrm{H}$ NMR spectra of both studied ligands, signals of the central methylene of the ring propylene group can be easily monitored as they are significantly distant from the other signals. Quartet of the methylene group of the trifluoroethyl moiety can be also assigned through entire pH range even if overlapping with other signals (it occurs in acid solutions). In addition in ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{L} 2$, the central methylene group of the propylene pendant arm can be also easily identified in entire pH range used in the titration. Simultaneously, chemical shift changes of triplet present in ${ }^{19} \mathrm{~F}$ NMR with pH were also analysed. The best fits of the experimental data are shown on Figure S14. The data clearly showed that the first two protonations occur in alkaline region (attributable to double protonation of the cyclam skeleton) with $\log K(\mathbf{H L} \mathbf{1})=10.79(2)$ and $\log K\left(\mathrm{H}_{2} \mathbf{L} \mathbf{1}\right)=8.74(3)$, and $\log K(\mathrm{H} \mathbf{L} \mathbf{2})=11.5(2)$ and $\log K\left(\mathrm{H}_{2} \mathbf{L} \mathbf{2}\right)=9.12(9)$.
Overall basicity of the macrocycle ring in both ligands, $\log \beta_{2}(\mathbf{L} 1)=19.53$ and $\log \beta_{2}(\mathbf{L} 2)=20.62$, is lower than that of cyclam itself $\left(\log \beta_{2}(\text { cyclam })=21.48\right)^{[7]}$ or its phosphonate derivatives, ${ }^{[8,9,10]}$ but it is comparable to other cyclam derivatives as e.g. $N, N^{\prime}, N^{\prime \prime}, N^{\prime \prime \prime}-\mathrm{Me}_{4}$ cyclam (18.38) ${ }^{[11]}$ or $\mathrm{H}_{4}$ teta (20.75). ${ }^{[12]}$ The lower basicity of $\mathbf{L 1}$ compared to $\mathbf{L} 2$ results from the shorter spacer between the macrocycle and the lectron-withdrawing substituent in the pendant arm. The third and fourth protonations obviously occur on the amino groups of the pendant arms as the processes are associated with significant chemical shift changes in ${ }^{19}$ F NMR spectra and those of methylene of the trifluoroethyl moiety in ${ }^{1} \mathrm{H}$ NMR spectra. The " pH " dependence of the signal positions can be only successfully fitted if one common constant for both protonation steps was considered. It points that the protonations of these very distant amino groups do not mutually influence each other and both pendant arms behave independently. The fits gave protonation constants $\log K\left(\mathrm{H}_{3} \mathbf{L} \mathbf{1}\right)=\log K\left(\mathrm{H}_{4} \mathbf{L} \mathbf{1}\right)=4.07(1)$ and $\log K\left(\mathrm{H}_{3} \mathbf{L} 2\right)=\log K\left(\mathrm{H}_{4} \mathbf{L} \mathbf{2}\right)=4.82(1)$, respectively. Also in this case, length of the spacer (ethylene vs. propylene) between cyclam ring and the pendant amino group is reflected, leading to the lower basicity to $\mathbf{L 1}$.

Figure S14. The pH dependence of selected signals found in ${ }^{1} \mathrm{H}$ and ${ }^{19} \mathrm{~F}$ NMR spectra of $\mathbf{L} \mathbf{1}$ (left) and $\mathbf{L} \mathbf{2}$ (right) in $\mathrm{D}_{2} \mathrm{O}$. Vertical dashed lines show values of $\log K_{\mathrm{a}}\left(\mathrm{H}_{n} \mathbf{L}\right)$. Colour codes: ${ }^{1} \mathrm{H}$ : blue and violet are two central lines of the quartet of $\mathrm{CH}_{2} \mathrm{CF}_{3}$ group ( ${ }^{3} \mathrm{JHF}_{\mathrm{HF}}$-coupling), red lines are central $\mathrm{CH}_{2}$ group of the cyclam propylene unit, brown line is central $\mathrm{CH}_{2}$ group of the pendant propylene unit. ${ }^{19} \mathrm{~F}$ : three colours represent individual lines of triplet of the $\mathrm{CH}_{2} \mathrm{CF}_{3}$ group ( ${ }^{3} J_{\mathrm{HF}}$-coupling). Crosses represent measured data, lines represent the best fits. The " pH " means direct reading of combined glass electrode (calibrated using standard buffers) immersed in $\mathrm{D}_{2} \mathrm{O}$ solution of the samples.

## Changes of visible spectra of $\mathbf{C u}(\mathrm{II})-\mathrm{L} 1, \mathrm{Cu}(\mathrm{II})-\mathrm{L} 2$ and $\mathrm{Cu}(\mathrm{II})-\mathrm{L} 3$ systems with time

Upon mixing of all three ligands $\mathbf{L 1} \mathbf{- L 3}$ with a $\mathbf{C u}(\mathrm{II})$ salt in acid aq. solution, deep blue colour was gradually developed. Upon standing the solutions at pH 3.0 , colour gradually obtains reddish-violet tinge. It can be demonstrated by change in absorption spectra of the $\mathbf{C u}($ II $)-\mathbf{L} 1$ system shown in Figure S 15 where absorption band maximum gradually shifted from initial 565 to 550 nm during $c a$. three weeks and, then, the spectrum remains unchanged indicating that resulting violet-blue solution is fully equilibrated. The band maximum shift was also accompanied with some band narrowing. When pH of the equilibrated mixture (after 30 d ) was raised to 10 , the maximum of absorption band was shifted to higher energies ( 540 nm ) and the band was slightly broadened in the long-wavelength part of the spectrum (Figure S15). This spectral change was fast (in the timescale of pH readjustment and spectra recording) and reversible - upon decreasing pH back to 3.0 , the same spectrum as the original one before the pH increase was obtained. If pH the freshly mixed $\mathrm{Cu}(\mathrm{II})-\mathbf{L} \mathbf{1}$ system was increased to 7.4 , the equilibrium was reached during one week. If the initial pH was 10 , the colour change was completed overnight. In both these additional experiments, essentially the same absorption spectra were obtained for equilibrated solutions as in the first experiment (equilibration at pH 3 and later increase to pH 10 ) discussed above.

Figure S 15 . Time change of absorption spectra of the $\mathrm{Cu}(\mathrm{II})-\mathbf{L 1}$ system at pH 3 , and comparison with the spectrum of the equilibrated mixture at pH 10 . Spectra were scaled to same absorbance at maximum of the absorption bands to enable direct comparison of the band shapes.

The systems $\mathbf{C u}($ II $)-\mathbf{L} \mathbf{2}$ and $\mathbf{C u}($ II $)-\mathbf{L} \mathbf{3}$ behaved similarly. A colour change is much slower in the acid solutions compared to the neutral or alkaline ones. Spectra of fresh $\mathbf{C u}($ II $)-\mathbf{L} 2 / \mathbf{C u}($ II $)-\mathbf{L 3}$ mixtures and that of the equilibrated solutions are shown in Figure S16.

Figure S16. Change of absorption spectra of the $\mathrm{Cu}(\mathrm{II})-\mathbf{L} \mathbf{2}$ (left) and $\mathrm{Cu}(\mathrm{II})-\mathbf{L 3}$ (right) systems at pH 3 with time, and comparison with the spectra of the equilibrated mixture at pH 10 . Spectra were scaled to same absorbance at maximum of the absorption bands to enable direct comparison of the band shapes.

## Changes of ${ }^{19} \mathrm{~F}$ NMR spectra of $\mathrm{Cu}($ II $)-\mathrm{L} 1$ system with time

Figure S17. Changes of ${ }^{19} \mathrm{~F}$ NMR spectra of the $\mathrm{Cu}(\mathrm{II})-\mathbf{L} 1$ system with time $\left(\mathrm{pH} 7.4,50^{\circ} \mathrm{C}, 376.1 \mathrm{MHz}\right)$.

## Changes of ${ }^{19} \mathrm{~F}$ NMR spectra of $\mathrm{Cu}(\mathrm{II})-\mathrm{L} 1 / \mathrm{L} 2 / \mathrm{L} 3$ complexes with pH

Figure S18. Dependence of ${ }^{19} \mathrm{~F}$ NMR spectra of the $\mathbf{C u}(\mathrm{II})-\mathbf{L 1}$ system on $\mathrm{pH}\left(25{ }^{\circ} \mathrm{C}, 376.1 \mathrm{MHz}\right)$. Signals of individual complex species are labelled by I and III, and signal of the ligand excess is labelled by asterisk (*).

Figure S19. Dependence of ${ }^{19} \mathrm{~F}$ NMR spectra of the $\mathrm{Cu}(\mathrm{II})-\mathbf{L} 2$ system on $\mathrm{pH}\left(25^{\circ} \mathrm{C}, 376.1 \mathrm{MHz}\right)$. Signal of the ligand excess is labelled by asterisk (*).

Figure S20. Dependence of ${ }^{19} \mathrm{~F}$ NMR spectra of the $\mathrm{Cu}(\mathrm{II})-\mathbf{L} 3$ system on $\mathrm{pH}\left(25^{\circ} \mathrm{C}, 376.1 \mathrm{MHz}\right)$. Signal of the ligand excess is labelled by asterisk (*).

Figure S21. Comparison of ${ }^{19} \mathrm{~F}$ NMR spectra of the $\mathbf{C u}(\mathrm{II})-\mathbf{L} 1, \mathrm{Cu}(\mathrm{II})-\mathbf{L} 2$ and $\mathbf{C u}(\mathrm{II})-\mathbf{L 3}$ systems at pH 1.0 . Blue line: mixtures equilibrated at neutral pH just after adjustment to pH 1.0. Red line: the same sample after two weeks at pH 1.0. The ligand excess is labelled by asterix.

## Determination of dissociation constants of the ligands and complexes in $\mathbf{H}_{\mathbf{2}} \mathrm{O}$

Dependence of chemical shifts on pH was fitted by OPIUM program package. ${ }^{[6]}$

Figure S22. The pH dependence of signals in ${ }^{19} \mathrm{~F}$ NMR spectra of $\mathbf{L 3}$ (left) and the $\mathrm{Cu}(\mathrm{II})-\mathbf{L} \mathbf{3}$ complex (right) in $\mathrm{H}_{2} \mathrm{O}$. The vertical dashed lines show values of $\log K_{\mathrm{a}}\left(\mathrm{H}_{3,4} \mathbf{L} \mathbf{3}\right)$ and $\log K_{\mathrm{a}}\left(\mathrm{CuH}_{1,2} \mathbf{L} \mathbf{3}\right)$.
