Microkinetic modeling methods

In this study, we employed a microkinetic framework based on the Sabatier analysis\(^1\) to find an upper bound of the overall reaction rate of Hg\(^0\) oxidation. The Sabatier rate\(^1\) is the reaction rate when each elementary reaction is assumed to be optimal, which can well reflect the catalytic reaction ability of the surface. This process is similar to the previously reported modeling for oxidation reactions\(^2, 3\). Based on the discussions in the main text, the reaction of Hg\(^0\) oxidation can be divided into the following four elementary steps:

\[
\begin{align*}
O_2 + * & \rightleftharpoons O_2* & \text{(R1)} \\
O_2* + Hg & \rightleftharpoons HgO* & \text{(R2)} \\
HgO* + Hg & \rightleftharpoons (HgO)_2* & \text{(R3)} \\
(HgO)_2* & \rightleftharpoons (HgO)_2 + * & \text{(R4)}
\end{align*}
\]

where R1 is assumed to be in equilibrium. The forward rate constants of the remaining steps are given by:

\[
k_i = v_i \exp \left[ \frac{-\Delta G_{ai}}{RT} \right] = v_i \exp \left[ \frac{- (E_{ai} - T \Delta S_{ai})}{RT} \right],
\]

where \(v_i\) is the prefactor, \(E_{ai}\) is the activation energy, and \(\Delta S_{ai}\) is the entropy difference between the transition state and the initial state, \(k\) is the Boltzmann constant, and \(T\) is the temperature. \(v_i\) is estimated by \(kT/\hbar\), where \(\hbar\) is the Planck’s constant.

Assuming R1 is in equilibrium, this gives:

\[
\theta_{O_2} = \frac{1}{1 + K_1 p(O_2)},
\]

where \(K_1\) is the equilibrium constant of R1, \(p(O_2)\) is the partial pressure of O\(_2\). \(K_1\) was calculated by:

\[
K_1 = \exp \left[ \frac{-G_1}{kT} \right],
\]

where \(G_1\) is the free energy of R1. The Sabatier rate \(r_i^{\text{max}} = \theta_i k_i\) of the overall
reaction ($r^S$) was estimated by the minimum reaction rate among R2-R4 as a function of O adsorption energy:

$$r_S = \min\{r_2^{S_{max}}, r_3^{S_{max}}, r_4^{S_{max}}\}.$$

Finally, the volcano activity plot is plotted as:

$$A = kT \ln\left(\frac{r_S h}{kT}\right).$$
