## Optimization studies for the semi-hydrogenation of phenylacetylene (PA) to styrene (ST) with Pd@PDA@PUF in EtOH at RT

All successive experiments were carried out with the same Pd@PDA@PUF foam of *ca.* 8 cm<sup>3</sup> whose mass was adjusted in function of its Pd content to have a Pd loading of 7 µmol. The two first trials, run with a Pd loading of 0.46 mol% and a H<sub>2</sub> flow of 13 mL/min, displayed similar reaction kinetics, with 98% conversion of PA and 97% selectivity to ST after 3.3 h for the 1<sup>st</sup> run (TON = 213, TOF = 65 h<sup>-1</sup>), and 93% conversion and 90% ST selectivity after 3 h in the 2<sup>nd</sup> run (TON = 202, TOF = 67 h<sup>-1</sup>) (Table S1, entries A and B). Once all alkyne had been consumed, the selectivity began to drop down as over-hydrogenation occurred (Fig. S6A and S6B). In view of these encouraging results, notably the little acceleration of the reaction kinetics between the two runs, we performed a third run under the same conditions. As can be seen in Figure S6C, we again observed a very selective conversion of PA to ST without any appreciable competition of further hydrogenation of the latter to give ethylbenzene (EB) until all PA had been consumed. Thus, 97% conversion was reached in 3 h with a ST selectivity of 88% (TON = 211, TOF = 70 h<sup>-1</sup>) (Table S1, entry C). In the 4<sup>th</sup> run, the rate of H<sub>2</sub> flow was decreased from 13 to 2 mL/min in order to map out its influence on the catalytic performance. No positive effect was observed on the hydrogenation selectivity, as only 94% ST selectivity at 81% PA conversion was observed after 2 h reaction and as it dropped similarly once all PA was consumed (Figure S6D and Table S1, entry D). We thus maintained the H<sub>2</sub> flow rate to 13 mL/min for the next two experiments, but increased the reactant's concentration to 3 and 6 mmol, conversely decreasing the catalyst loading from 0.46 mol% to 0.23 mol% in the 5<sup>th</sup> run (Figure S6E) and to 0.11 mol% in the 6<sup>th</sup> run (Figure S6F). Remarkably, the Pd@PDA@PUF catalyst maintained a very high chemoselectivity with higher kinetics in the 5<sup>th</sup> run, achieving as high as 91% conversion with 95% selectivity to ST after 2 h (TON = 396; TOF = 197 h<sup>-1</sup>) (Table S1, entry E). Again, ST hydrogenation to EB occurred appreciably only after full consumption of PA. When the substrate loading was doubled again to 6 mmol, the selectivity and the turnover frequency gratifyingly maintained to the same level, with 98% PA conversion with 94% selectivity after 4.25 h, thus giving a TON of 891 and a TOF of 210 h<sup>-1</sup> (Table S1, entry F). The latter conditions were chosen as the standard conditions.

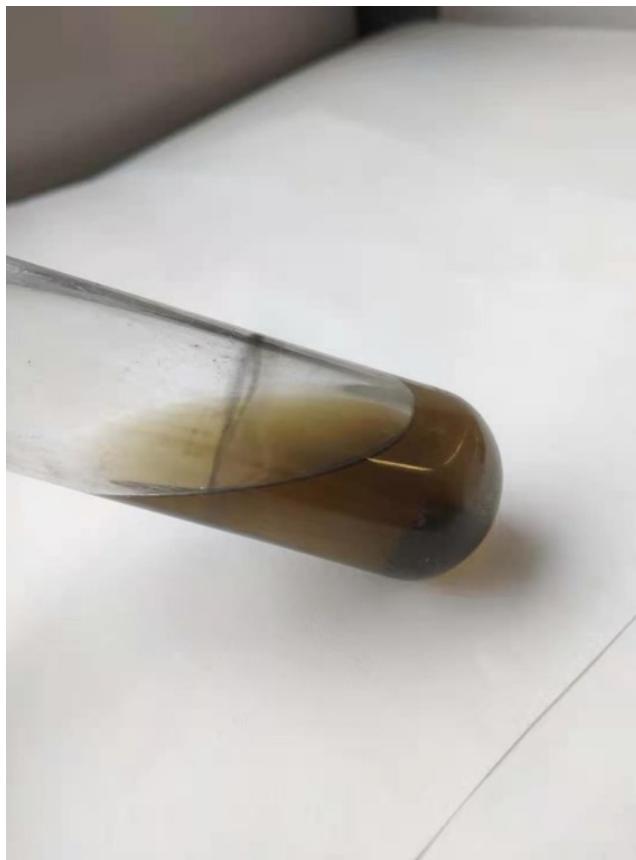

**Figure S6.** Kinetic monitoring of the optimization tests of PA semi-hydrogenation with Pd@PDA@PUF (ca. 8 cm<sup>3</sup>, Pd content 7.00.10<sup>-3</sup> mmol) in EtOH (20 mL) at RT under 625 rpm. **A, B, C:** PA (1.52 mmol), H<sub>2</sub> (13 mL/min); **D:** PA (1.52 mmol), H<sub>2</sub> (2 mL/min); **E:** PA (3 mmol), H<sub>2</sub> (13 mL/min); **F:** PA (6 mmol), H<sub>2</sub> (13 mL/min). Black curves: PA conversion. Red curves: selectivity to ST. Blue curves: selectivity to ethylbenzene (EB).

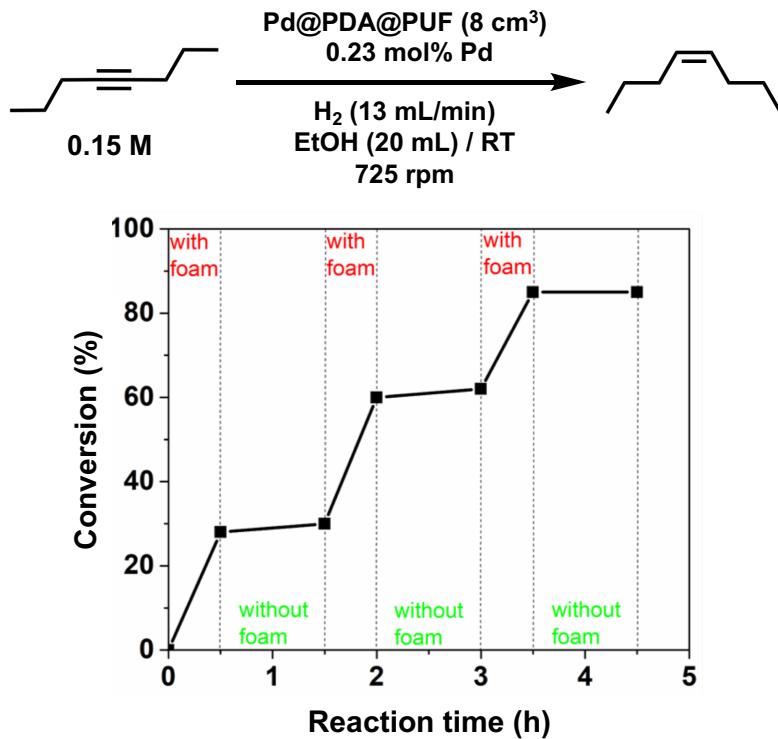

**Table S1.** Results of optimization tests of PA semi-hydrogenation to ST.

Entry	Cat. loading (Pd mol%)	H <sub>2</sub> flow speed	Time (h)	Conv. (%) <sup>a</sup>	Select. (%) <sup>a</sup>	TON <sup>b</sup>	TOF (h <sup>-1</sup> )
<b>A</b>	0.46	13	3.3	98	97	207	63
<b>B</b>	0.46	13	3	93	90	182	61
<b>C</b>	0.46	13	3	97	88	186	62
<b>D</b>	0.46	2	2	81	94	166	83
<b>E</b>	0.23	13	2	91	95	376	188
<b>F</b>	0.12	13	4.25	98	95	776	183

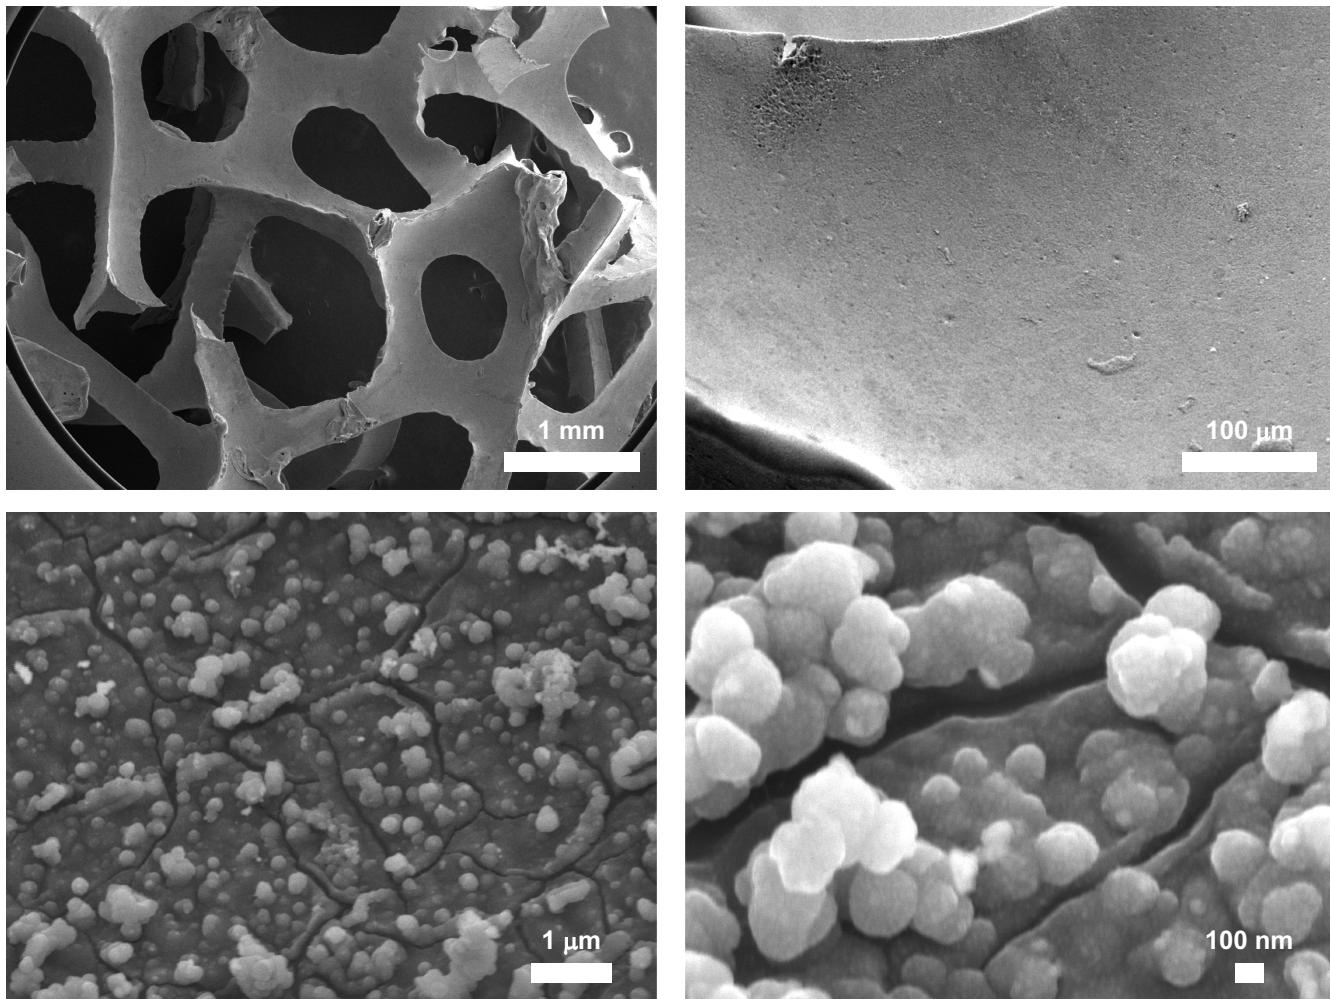

<sup>a</sup> PA conversion and ST selectivity were determined by GC analysis. <sup>b</sup> Turnover number expressed as mol of PA converted to ST vs. the catalytic loading.
