29 1. Materials and methods

30 1.1. Orthogonal test

The factors and levels of the orthogonal test were shown in Table S1. Since the orthogonal experiment involved 6 factors and 5 levels, the orthogonal table ($L_{25}(5^6)$) as shown in Table S2 was designed. Then, the factors and levels were corresponding to the orthogonal table ($L_{25}(5^6)$) to obtain the experimental program, as shown in Table S3.

40 1.2. Stability test of Ag NPs@PA

41 1.2.1. Stability of storage

In order to clarify the storage stability of Ag NPs@PA sol at 4 °C, in this experiment, the sols stored at 4 °C for different times (0, 1, 3, 5, and 6 weeks) were tested using UV spectrophotometer. The samples were diluted 20 times for each test, and three parallel experiments were performed and the average value was taken. The relative stability is the ratio of the absorption peak intensity of each test to the absorption peak intensity of the initial storage time.

48 1.2.2. pH stability

To verify the stability of Ag NPs@PA under different harsh conditions, some 49 experiments were carried out on the sol under different pH environments¹. Firstly, 50 deionized water with different pH (6-14) was configured. The samples were then 51 diluted 20-fold with deionized water of different pH, and the mixture was incubated for 52 2 hours at room temperature. Finally, the mixture was transferred to a quartz cuvette for 53 54 absorbance measurement, and three parallel experiments were performed for each group and the average value was taken. The highest value was defined as 100% relative 55 stability. 56

57 1.2.3 Stability of temperature

In addition to different pH environments, further experiments were carried out at different temperatures ¹. The samples were first diluted 20-fold, and then the dispersions were incubated at different temperatures (4, 25, 30, 60, 70 °C) for 2 h. Finally, absorbance measurements were performed in a quartz cuvette. Similarly, three parallel experiments were performed for each group and the average value was taken. The 63 highest value was defined as 100% relative stability.

64 1.3. Selectivity of electrochemical H₂O₂ sensors

65 The time-current test was used to detect 6 substances including 0.1 mM H_2O_2 , 1 66 mM NaCl, 1 mM citric acid (CA), 1 mM urea, 1 mM glucose (Glu) and 1 mM ascorbic 67 acid (AA) using sensors. The test potential was -0.5 V vs SCE.

68 1.4. Anti-interference of electrochemical H₂O₂ sensor

69 Sensors were used to detect the changes of the electrochemical response signal of
70 1 mM H₂O₂ in the presence and absence of 1 mM NaCl, 1 mM citric acid, 1 mM urea,
71 1 mM glucose and 1 mM ascorbic acid.

72 1.5. Repeatability and reproducibility of electrochemical H₂O₂ sensors

The same sensor was used to detect 1 mM H_2O_2 for four times, and the electrochemical response signal was compared to verify the repeatability of the sensor. In addition, three electrodes were made by the same method to detect 1 mM H_2O_2 , and the relative standard deviation (RSD) was calculated to study the reproducibility of the sensor.

78 1.6. Test of electrochemical H₂O₂ sensor in real samples

In order to evaluate the feasibility of the simple electrochemical H_2O_2 sensor in practical application, this sensor was used to detect the electrochemical response signal when 500 μ M H_2O_2 was added to real samples such as purified water, tap water and Fenhe water, and the recovery rate of each water sample was studied.

83 2. Results and discussion

84 2.1. Optimization of preparation conditions for Ag NPs@PA

85

86 2.2. Morphology of Ag NPs@PA

Figure S1. SEM images of Ag NPs@PA at (a) 100000、 (b) 200000 magnification times and their
(c) particle size distribution.

Figure S1a, b displayed SEM images of Ag NPs@PA at different magnifications. It can be seen from the figure that the morphology of Ag NPs@PA is almost spherical, and the particles are monodisperse, which was the same as the conclusion obtained in TEM. In addition, statistics were also carried out for the nanoparticles in Figure S1b, and the particle size distribution results were shown in Figure S1c. The particle size distribution ranged from 3-17 nm and the average particle size is 9.05 nm, which was consistent with the conclusion of TEM.

97 2.3. Stability of Ag NPs@PA

98

Figure S2. (a)ZETA potential of Ag NPs@PA and their stability under different conditions:
(b)time, (c)pH, (d)temperature.

The stability of sol is closely related to the convenience of storage and further application. It has been reported that nanoparticle sol is stable when its ZETA potential range is beyond ± 20 mV². Figure S2a exhibited that the ZETA potential of the Ag NPs@PA sol is -33.7 mV, indicating that the Ag NPs@PA sol has sufficient stability, which was the result of PA acting as dispersant and stabilizer to play a steric hindrance and the same charge repulsion between particles to avoid agglomeration.

107 In addition, as shown in Figure S2b, the Ag NPs@PA sol was continuously 108 monitored for 6 weeks, and it was found that the relative stability of the sol remained above 80% after 5 weeks, which also indicated that the sol was very stable. This storage stability also depended on the effective coating of Ag NPs by PA and was significantly affected by the antioxidant properties of PA molecules. Its antioxidant ability was derived from the fact that each PA molecule can provide 6 pairs of hydrogen atoms to form a stable structure for the electrons of free radicals, thus replacing Ag NPs as the oxidized molecules.

In order to investigate the stability of the sol in practical application, two external 115 environmental factors such as pH and temperature were also arranged to test the Ag 116 NPs@PA sol. As can be seen from Figure S2c, the relative stability of the sol was much 117 higher than 80% in the wide range (pH=6-14) of weak acid, neutral and basic, 118 indicating that the sol has a strong environmental adaptability in terms of pH. This is 119 because PA had a high degree of ionization in the pH range of weak acid, neutral and 120 121 basic. The strong electrostatic repulsion between the PA coated on the surface of different Ag NPs ensured the stability of Ag NPs@PA. Figure S2d showed the stability 122 test of Ag NPs@PA sol at different temperatures. No matter in low temperature storage 123 environment, room temperature or near high preparation temperature, its relative 124 stability was much higher than 80%, indicating that its stability did not depend on 125 external temperature. Under the low temperature storage environment of 4 °C, the free 126 127 movement of particles was very inactive, and agglomeration was difficult to occur under the obstruction of PA. With the increase of external temperature, the Brownian 128 motion intensified and the probability of collision between particles increased. 129 However, since Ag NPs were coated by PA, the agglomeration phenomenon was not 130 obvious. 131

132 2.4. Selectivity of electrochemical H₂O₂ sensors

133 134

Figure S3. Selectivity of sensor.

To study the selectivity of the electrochemical H_2O_2 sensor, the sensor was used to detect H_2O_2 , NaCl, citric acid, urea, glucose and ascorbic acid, as shown in Figure S3. It can be found from the response signal in the figure that even though the concentration of H_2O_2 was only 1/10 of the other interfering substances, its response signal was still much stronger than NaCl, citric acid, urea, glucose and ascorbic acid, which was enough to manifest that the sensor has excellent selectivity for the detection of $H_2O_2^{-3}$.

142 2.5. Anti-interference of electrochemical H₂O₂ sensor

143

144

Figure S4. Anti-interference of electrochemical H₂O₂ sensor

Besides selectivity, the anti-interference ability of the sensor was also investigated. Figure S4 exhibited the comparison of the response signals of the sensor to detect H_2O_2 with or without interference. It can be seen intuitively that the response signal detected by the electrochemical H_2O_2 sensor had little change in the presence or absence of interfering substances, which confirmed that the sensor demonstrated excellent antiinterference ability for the detection of H_2O_2 , which was conducive to its further

151 practical application.

152 2.6. Repeatability and reproducibility of electrochemical H₂O₂ sensors

Figure S5. Repeatability of the sensor

155 Figure S5 revealed that the electrochemical H₂O₂ sensor possesses good repeatability. The response signal corresponding to the same sensor detecting the same 156 concentration of H₂O₂ kept basically consistent, and the RSD of four tests was only 157 1.58%, indicating that the sensor has good repeatability and can carry out continuous 158 159 detection, which was of great significance for field detection. Reproducibility is another important sensor performance parameter. Reproducibility is another important sensor 160 performance parameter. The RSD of three electrodes made by the same method to 161 detect the same concentration of H₂O₂ was 3.83%. Therefore, the reproducibility of the 162 163 electrochemical H₂O₂ sensor was also acceptable.

164 2.7. Application of electrochemical H₂O₂ sensor in real samples

165 Table S5. Recovery rate (%) of H_2O_2 detected by electrochemical H_2O_2 sensor in actual samples.

| Sample | H_2O_2 recovered (μL) | Recovery rate (%) | RSD (%) |
|----------------|--------------------------------|-------------------|---------|
| PBS | 500.0 | 100% | 0 |
| Purified water | 504.5 | 100.09% | 0.63 |
| Tap water | 505.1 | 101.02% | 0.72 |
| Fenhe water | 463.8 | 92.76% | 5.31 |

166 To evaluate the feasibility of the sensor in practical application, the 167 electrochemical H_2O_2 sensor was used to detect the actual samples of purified water, 168 tap water and Fenhe water ³. A standard concentration of 500 μ M H_2O_2 was added to a given actual water sample, and the recovery of each water sample was researched, as
shown in Table S5. It is observed from the table that the recovery rate of the sensor in
the three practical samples was relatively ideal, ranging from 92.77% to 101.02%,

- 172 which can be applied in practical detection.
