## Experimental Section

**Materials and General Methods.** All chemical reagents were commercially purchased from Jinan Heng hua Sci. & Tec. Co. Ltd. without any further refinement. Thermogravimetric analyses (TGA) were performed on NETZSCH STA 449 F3 thermogravimetric analyzer (25-800 °C, 10 °C/min). The catalytic yield was calculated and measured on a Thermo Fisher Trace ISQ GC/MS instrument. ICP measurements were performed by a (thermofisher) iCAP Qc ICP-MS emission spectrometer. Temperature-programmed desorption (TPD) experiments were performed in VDsorb-91i. Prior to TPD, about 100mg of the catalysts were pretreated for 2 hours in 20 mL/min Ar gas flow at 250 °C. After being cooled to 100 °C, CO<sub>2</sub> or NH<sub>3</sub> absorbed for 2 hours; then, the sample was treated again for 1 hour in 20 mL/min Ar gas flow. Finally, the sample was heated up to 500 °C at a rate of 10 °C/min in the atmosphere of Ar. The desorbed gases were detected by thermal conductivity detector (TCD).

**X-ray crystallography.** A summary of crystallographic data, refinement parameter and bond lengths and angles for **NUC-56** were given in Table S1 and S2. The diffraction intensity data for **NUC-56** was obtained at 566(2) K by using a Bruker Smart-APEX II CTM area detector (Mo-K $\alpha$  radiation,  $\lambda = 0.071073$  nm) with graphite-monochromated radiation. The data integration and reduction were processed with SAINT software. The reflection data were consequently corrected for empirical absorption corrections and Lorentz and polarization effects. The structure was solved by direct methods and refined by full-matrix least-squares with the SHELXL package. All non-hydrogen atoms were refined anisotropically, until convergence was attained. Hydrogen atoms except those on water molecules were generated geometrically with fixed isotropic thermal parameters, and included in the structure factor calculations. The block of SQUEEZE in PLATON was employed to eliminate the highly disordered solvent molecular. Further details on the crystal structure investigations may be obtained from the Cambridge Crystallographic Data Centre, with the depository number CTMC-2168334 for **NUC-56**.

**Catalytic Experiment Operation.** The catalytic cycloaddition reaction of CO<sub>2</sub> with different epoxy compounds were performed under the optimal reaction conditions in 20 mL around-bottom flask reactor, including 0.5 mol% **NUC-56a** catalyst (0.10 mol %, based on the active In(III) and Tm(III) centers), 1atm CO<sub>2</sub> pressure at 65 °C for 7h with a 5.0% mol *n*-Bu<sub>4</sub>NBr. CO<sub>2</sub> gas was slowly purged into the reactor until the reaction was over. Eventually, the productivity of cyclocarbonate was estimated by GC-MS analysis through using an internal standard of *n*-dodecane (18 mmol), and the separated products were analyzed by <sup>1</sup>H NMR in DMSO-*d*<sub>6</sub> solution in all the catalytic reactions. For the Knoevenagel condensation reaction, benzaldehyde (20 mmol), malononitrile (10 mmol), and activated **NUC-56a** (0.4 mol %, based on the In(III) and Tm(III) centers) of 3 mL of ethanol were transferred into a 10 mL closed reaction tube with magnetic stirring for 6 h at 65 °C. After the reaction, the transformed product was determined by gas chromatography and <sup>1</sup>H NMR spectroscopy. The catalytic yield of this Knoevenagel condensation reaction was verified by GC-MS using an internal standard of *n*-dodecane (15 mmol), and the <sup>1</sup>H NMR spectroscopy of products were recorded in Chloroform-*d* solution.

### Isosteric Heat Calculation.

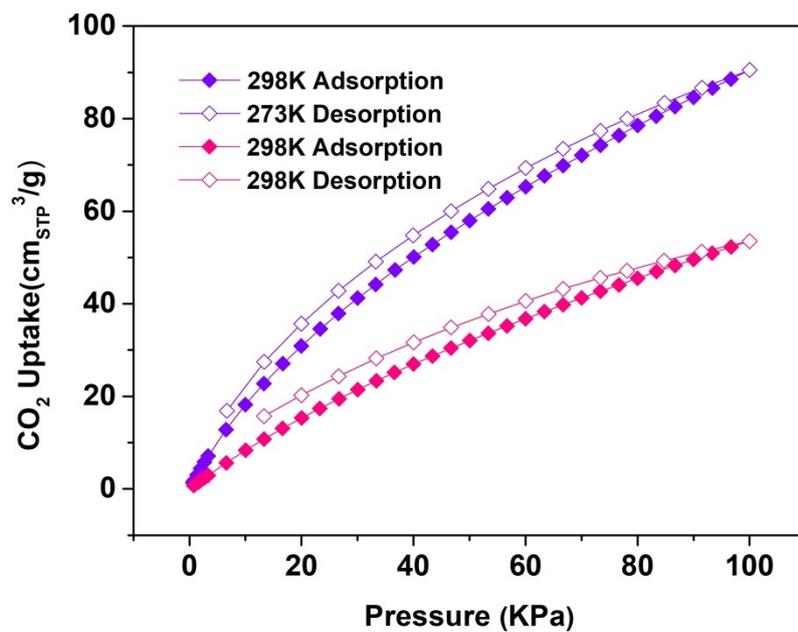

The  $Q_{st}$  value is a parameter that describes the average enthalpy of adsorption for an adsorbing gas molecule at a specific surface coverage and is usually evaluated using two or more adsorption isotherms collected at similar temperatures. The zero-coverage isosteric heat of adsorption is evaluated by first fitting the temperature-dependent isotherm data to a virial-type expression, which can be written as:

$$\ln p = \ln N + \frac{1}{T} \sum_{i=0}^m a_i N^i + \sum_{j=0}^n b_j N^j$$

**N**: Adsorption capacity (mg/g); **p**: Pressure (mmHg); **T**: Temperature (K); **a<sub>i</sub>** , **b<sub>j</sub>** : Empirical constant; **R** : Universal gas constant (8.314 J·mol<sup>-1</sup>·K<sup>-1</sup>)

The isosteric enthalpy of adsorption ( $Q_{st}$ ) :

$$Q_{st} = -R \sum_{i=0}^m a_i N^i$$

**Figure S10.** The CO<sub>2</sub> adsorption and desorption isotherms for NUC-56a at 273K and 298K. Filled symbols: adsorption; Open symbols: desorption.

### Yield Calculation Based on the GC-MS Analysis

Gas chromatography mass spectrometry (GC-MS) analyses were executed on a time-of-flight Thermo Fisher Trace ISQ GC/MS instrument, the yield (%) was calculated based on the consumption of starting material using the equation:

$$\text{Yield (\%)} = \left( \frac{\frac{\text{area of reactant at 0 hour}}{\text{area of internal standard at 0 hour}} - \frac{\text{area of reactant at any time}}{\text{area of internal standard at any time}}}{\frac{\text{area of reactant at 0 hour}}{\text{area of internal standard at 0 hour}}} \right)$$
