2. Experimental

2.5. Characterization

The single-crystal X-ray diffraction data were collected using a SMART APE II DUO X-ray four-circle single-crystal diffractometer (Bruker) equipped with a CCD-detector, a graphite monochromator, and a Cu K radiation source. The powder X-ray diffraction (PXRD) patterns of the crystals were collected on a Bruker (Karlsruhe, Germany) D8 Advance XRD with graphite monochromatized Cu K α radiation ($\lambda = 0.15418$ nm) in the two degrees range from 10-80°. High-resolution transmission electron microscopy (HRTEM) observation was performed by using a JEOL 2100F high-resolution transmission electron microscope using an accelerating voltage of 200 kV with an attached energy-dispersive x-ray energy dispersive spectrum spectrometer (EDS). The chemical composition on the surface of the particles was analyzed by using x-ray photoelectron spectra (XPS) conducted on a ESCALAB 250Xi versa

probe spectrometer (analyzer resolution ≤ 0.5 eV) with a monochromatic of Al K α radiation ($h\nu = 486.6$ eV). The photoluminescence (PL) excitation and PL emission spectra were recorded on a FluoroMAX-4-TCSPC fluorescence spectrophotometer (Horiba Jobin Yvon Inc). The PL decay curves were recorded on an FLS980 spectrometer (Edinburgh).

2.6. Computational Methodology

The first-principles density functional theory (DFT) computation was implemented by Vienna Ab initio Simulation Package (VASP).¹ Generalized gradient approximation (GGA) in the Perdew Burke Ernzerhof (PBE) form was employed for the exchange-correlation functional energies.² The cut-off energy was set at 350 eV for the plane wave basis set. For undoped samples, a $2 \times 2 \times 2$ G-centered mesh was selected for Brillouin-zone K-point sampling in the unit cell. For Sb³⁺-doped samples, a $1 \times 1 \times 1$ G-centered mesh was used in the supercell (i.e., $2 \times 2 \times 1$ primitive cells). The energy of the system and forces on each atom were converged to 10–5 eV and 0.003 eV/Å.
