## EXPERIMENTAL SECTION

### Characterization

Powder X-ray diffraction (PXRD) was collected at room temperature on a PANalytical Empyrean series 3 diffractometer equipped with Cu K $\alpha$  radiation. FT-IR spectra were recorded as KBr pellets using a Bruker Tensor 37 spectrometer with 4 cm $^{-1}$  resolution. X-ray photoelectron spectroscopy (XPS) data were recorded on a Thermo Scientific K-Alpha system. Al K $\alpha$  X-ray (6 mA / 12 KV) was utilized as the irradiation source. All XPS measurements were performed in the CAE mode with the reference of C 1s (284.8 eV). The nitrogen adsorption and desorption isotherm were measured at 77 K were measured at 298 K using a Micromeritics ASAP 2020 PLUS HD88 system. The samples were degassed at 90°C for 4 hours before the measurements. The thermogravimetric analysis (TGA) was performed on a ZRT-A thermogravimetric analyzer instrument under nitrogen atmosphere with a heating rate of 10°C/min. The metal content of TPPDA-CuPor-COF was determined by inductively coupled plasma (ICP) analysis with an Agilent 5110 ICP-OES instrument. The images of high-resolution field transmission electron microscopy (HR-TEM), high angle annular dark-field scanning transmission electron microscope (HAADF-STEM) and energy dispersive spectroscopy (EDS) mappings were collected by transmission electron microscopy (JEM-2100F) at an operation voltage of 200 kV. Scanning electron microscopy (SEM) images were obtained on a HITACHI SU8010 microscope. The transmission electron microscopy (TEM) image was acquired on HITACHI HT7700

with an electron acceleration energy of 100 kV. UV-vis diffuse reflectance absorption spectra (DRS) were recorded on a Shimadzu UV-2600 spectrophotometer with BaSO<sub>4</sub> as the reference.

### **Electrochemical Measurements**

Electrochemical lithium-storage properties of TPPDA-CuPor-COF were measured by using CR2032 coin-type test cells assembled in argon-filled glove box (the oxygen and water concentration maintained below 1 ppm). To fabricate the working electrode, a slurry with appropriate viscosity consisting of 50wt% active materials, 40wt% Super-P carbon and 10wt % PVDF binder dissolved in NMP was casted on the Al foil, drying at 100°C under vacuum for 24 h. The loading mass of electroactive materials in electrode slurry is about 0.8 mg/cm<sup>2</sup>. Pure lithium foil was used as the counter electrode, and 1mol/L LiPF<sub>6</sub> in EC/EMC (3:7 v/v) was served as the electrolyte, and a porous Celgard 2400 as separator. Galvanostatic charge/discharge cycles were performed in a potential range of 1.5 – 4.2 V vs. Li/Li<sup>+</sup> on a LAND 2001A instrument (Wuhan, China). CHI 660E electrochemical workstation (Shanghai, China) was used to record the CV and electrochemical EIS with a frequency range from 10<sup>-1</sup> to 10<sup>6</sup> Hz.

### ***Ex situ* XPS measurement and sample preparation**

When conducting *ex situ* XPS measurements of TPPDA-CuPor-COF, the coin cells were cycled to charged state (4.2 V) and discharged state (1.5 V), respectively. Then the coin cells were disassembled and the obtained electrodes were washed with THF

and dried in argon-filled glove box before tests.

### Structure modeling

The unit cells of the models were refined with the experimental PXRD data of TPPDA-CuPor-COF by using the Le Bail refinement. The cell parameters and the refined PXRD patterns were obtained until the values of  $R_{wp}$  and  $R_p$  converged.

### Calculations of theoretical capacity, energy density and power density

Theoretical capacity  $C_t$  (mA h g<sup>-1</sup>) was calculated using the following equation:<sup>1</sup>

$$C_t = \frac{nF}{3600(M_w/1000)}$$

Where  $n$  and  $M_w$  is the number of charge carrier and the molecular weight of the active material, respectively,  $F$  is the Faraday constant (96485 C mol<sup>-1</sup>).

In the TPPDA-CuPor-COF, the molecular weight of a repeating unit (C<sub>78</sub>H<sub>51</sub>N<sub>10</sub>Cu) is calculated to be  $M_w = 1191.88$  g mol<sup>-1</sup>. The number of electrons ( $n$ ) involved in the repeating unit is 6. Therefore, the theoretical capacity is calculated using the equation of  $C_t = 134.92$  mA h g<sup>-1</sup>.

The energy density ( $E$ ) of the electrode can be calculated based on the equation:

$E = C_{\text{capacity}} \times V_{\text{average}}$ , where  $C_{\text{capacity}}$  is the experimental specific capacity and  $V_{\text{average}}$  is the average output potential (vs. Li/Li<sup>+</sup>) of the electrode.

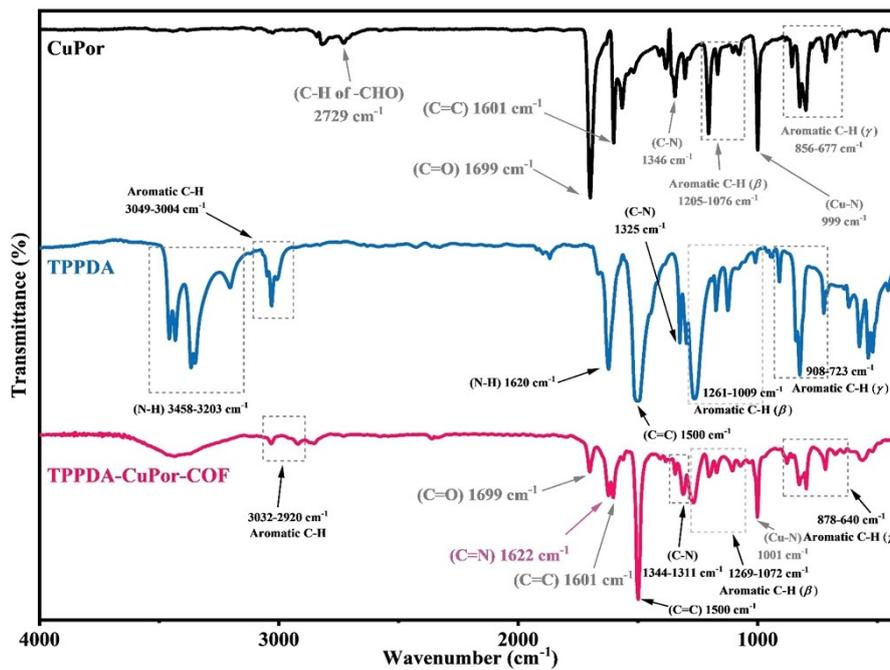

### DFT calculation methods

Density functional theory (DFT) calculations were performed by B3LYP-D3

method with Becke-Johnson damping.<sup>2,3</sup> The def2-SVP basis set was utilized to optimize the structures of the TPPDA-CuPor-COF repeat unit and the complexes, and the def2-SVPD basis set was applied to calculate the energies using Gaussian 09 program (version D.01).<sup>4,5</sup> The Molecular electrostatic potential (MESP) and differential charge analysis were carried out by Multiwfn software.<sup>6</sup> All visualization of MESP plots are performed by the Visual Molecule Dynamics (VMD) software.<sup>7</sup> The differential charge density ( $\Delta\rho$ ) was calculated by the formula:<sup>8</sup>

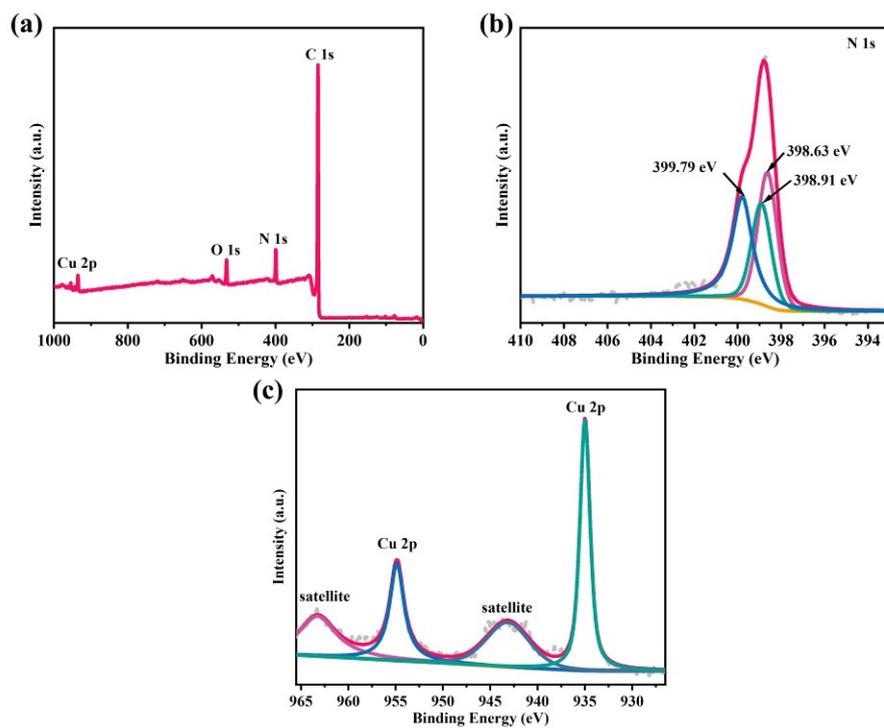

$$\Delta\rho(\text{PF}_6^-) = \rho(\text{TPPDA-CuPor} - x\text{e}^- + x\text{PF}_6^-) - x\rho(\text{PF}_6^-) - \rho(\text{TPPDA-CuPor}^{x+})$$

$$\Delta\rho(\text{Li}^+) = \rho(\text{TPPDA-CuPor} + x\text{e}^- + x\text{Li}^+) - x\rho(\text{Li}^+) - \rho(\text{TPPDA-CuPor}^{x-})$$
