1. Experimental section

1.1. Reagents and materials

Copper nitrate trihydrate ($\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$), trimesic acid ($\text{C}_9\text{H}_6\text{O}_6$, benzene-1,3,5-tricarboxylic acid), zinc nitrate hexahydrate ($\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$), 2-methylimidazole, cobalt nitrate hexahydrate ($\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$), iron chloride hexahydrate ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$), benzene-1,4-dicarboxylic acid (H_2BDC), N,N-dimethylformamide (DMF), zirconium chloride (ZrCl_4), acetic acid, o-phenylenediamine (OPD), hydrogen peroxide solution (H_2O_2 , 30%, w/w), glucose (GLU), ascorbic acid (AA), citric acid (CA), and uric acid (UA) were all purchased from Aladin Chemistry Co., Ltd. (Shanghai, China). Nafion (5%) was bought from Alfa Aesar (United States).

Cell counting kit-8 (CCK-8), calcein-AM/propidium iodide (PI) double staining kit, and dehydrogenate (DHE) solution were purchased from Beyotime Biotechnology (Nanjing, China). Phosphate buffered saline (PBS, 10 mM, pH 7.4) contained 136.7 mM NaCl, 2.7 mM KCl, 8.2 mM Na_2HPO_4 , and 1.8 mM KH_2PO_4 . All chemicals were of analytical grade and used without further purification.

1.2. Synthesis of five types of typical MOFs

HKUST-1(Cu) was prepared by reacting copper nitrate and trimesic acid. First, 1.82 g $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ and 0.875 g benzene-1,3,5-tricarboxylic acid were dissolved in 50 mL absolute methanol under ultrasonication. After that, the copper nitrate solution was transferred into the tricarboxylic acid solution, and the mixed solution was sonicated in an ultrasonic cleaner for 1 min. The mixture solution was kept at room temperature for 24 h until MOF precipitation finished. The precipitate was retrieved by centrifugation and washed with methanol 2-3 times. Finally, the blue powder of HKUST-1(Cu) was dried in a vacuum at 60 °C for 12 h.

ZIF-8(Zn) was prepared by reacting zinc nitrate and 2-methylimidazole. First, 0.595 g $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and 0.6575 g 2-methylimidazole were dissolved in a 50 mL absolute methanol under ultrasonication, respectively. After that, the zinc acetate solution was transferred into the 2-methylimidazole solution and the mixed solution was sonicated in an ultrasonic cleaner for 1 min. The mixture solution was kept at room temperature for 24 h to grow the standard ZIF-8 crystals with typical rhombic dodecahedron morphology. The product was collected by centrifugation and washed with methanol for 2-3 times. At last, the white powder of ZIF-8(Zn) was dried in vacuum at 60 °C for 12 h.

ZIF-67(Co) was prepared by reacting cobalt nitrate and 2-methylimidazole. First, 0.546 g $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and 0.616 g 2-methylimidazole were dissolved in a 30 mL absolute methanol under ultrasonication, respectively. After that, the cobalt nitrate hexahydrate solution was transferred into the 2-methylimidazole solution and the mixed solution was sonicated in an ultrasonic cleaner for 1 min. The mixture solution was kept at room temperature for 24 h to grow the standard ZIF-67 crystals. The purple product was collected by centrifugation and washed with methanol for 2-3 times. At last, the powder of ZIF-67(Zn) was dried in vacuum at 60 °C for 12 h.

MIL-101(Fe) was prepared by reacting iron chloride and H_2BDC with a solvothermal method. In a typical synthesis, 1.352 g $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, 0.415 g H_2BDC and 30 mL DMF were well mixed into a 50 mL Teflon-lined stainless steel autoclave and maintained at 120 °C for 24 h. The brown product was collected by centrifugation and washed with DMF, ethanol and ultrapure water for 2-3 times. At last, the powder of MIL-101(Fe) was dried in vacuum at 60 °C for 12 h.

UiO-66(Zr) was prepared by reacting zirconium chloride and H_2BDC with a solvothermal method. In a typical synthetic process, 0.080 g ZrCl_4 and 0.057 g H_2BDC were dissolved in 20 mL DMF by using ultrasound for 10 min. Then 3 mL of acetic acid was added into the solution to tune the morphology of the product. After further 10 min ultrasonic treatment, the obtained homogeneous solution was then transferred into a 40 mL Teflon-lined stainless steel autoclave and maintained at 120 °C for 24 h. Finally, the products were collected by centrifugation and washed with DMF, ethanol and ultrapure water for 2-3 times. The powder of UiO-66(Zr) was dried in vacuum at 60 °C for 12 h.

1.3. Synthesis of QHKUST-1

A glass vessel containing the HKUST-1 MOF powder was placed in a tube furnace under ambient air. The calcination experiment was carried out in airflow (50 mL/min) at a heating rate of 10 °C/min using an initial HKUST-1 mass of 50 mg. To investigate the phase after thermal treatment of HKUST-1, the calcination was performed at 200, 250, 300, 350, and 400 °C for 1 h. After confirming the HKUST-1 crystalline phase remained at 250 °C, the isothermal time of calcination was varied to 1, 2, 3, 4, and 5 h to control the distortion of the symmetric Cu dimer in HKUST-1.

1.4. Material characterization

Morphological features of the samples were studied using a field emission scanning electron microscope (SEM, Gemini500, Germany). Transmission electron microscopy (TEM) images were

obtained using a transmission electron microscope (JEM-1400, Japan), which was operated at an accelerating voltage of 200 kV. Fourier transform infra-red (FT-IR) was carried out by using a Fourier transformation infra-red spectrometer (IR, EQUINOX 55, Germany). The crystal phase of the prepared samples was characterized by X-ray diffraction (XRD) with X-ray powder diffractometer (Empyrean, Netherlands). X-ray photoelectron spectroscopy (XPS) for element state investigation was carried out by using a Thermo Scientific source XPS system (ESCALAB 250). Thermal behavior of HKUST-1 according to the temperature was investigated by a thermogravimetry (TG209F1 libra, Germany). Raman analysis was carried out by using a Renishaw microscope (inVia Qontor, England).

1.5. Catalase-like activity of MOFs

First, the catalase-like activity of MOFs was assayed by observing the generation of oxygen (O_2) through the catalytic decomposition of H_2O_2 as the substrate. The solutions in the tubes containing H_2O_2 and different types of MOFs were reacted at 37 °C for 30 min, and the photos were obtained.

Then, the detailed concentrations of H_2O_2 in different reaction conditions were estimated. The calibration curve of absorbance and the concentration of H_2O_2 (1–25 mM) were recorded by monitoring the absorbance at 240 nm with different concentrations of H_2O_2 . The H_2O_2 decomposition experiments were studied by adding different types of MOFs (1.0 mg mL^{-1}) into PBS solution containing H_2O_2 (10 mM) at 37 °C. After a period of time, the mixtures were centrifuged, and the ultraviolet–visible (UV-Vis) spectra of the remaining H_2O_2 were recorded on a UV–Vis spectrophotometer (UV-2600, Shimadzu, Japan).

1.6. Peroxidase-like activity of MOFs

The peroxidase-like activity of different types of MOFs was evaluated via the catalytic oxidation of the OPD at the assist of H_2O_2 in 10 mM PBS (pH 7.4). All the catalytic reactions were performed by monitoring the absorbance changes of OPD at 420 nm. In a typical test, chemicals were added into PBS buffer solution (10 mM, pH 7.0) in an order of MOFs, OPD (final concentration 8.0 mM), and H_2O_2 (final concentration 10.0 mM) under 37 °C. The peroxidase-like activities of MOFs were also investigated by varying the concentrations of OPD (1.0, 2.0, 4.0, 6.0, 8.0, and 10.0 mM), and H_2O_2 (1.0, 2.0, 4.0, 6.0, 8.0, and 10.0 mM). The peroxidase-like activities of different types of MOFs were assessed under the same standard conditions.

1.7. Electrochemical characterization of MOFs

All electrochemical measurements were carried out on a CHI 660E electrochemical workstation (Shanghai CHI Instrument Co., China) with a bare or modified glassy carbon electrode (GCE, 3 mm in diameter) as working electrode, a platinum wire as counter electrode, and an Ag/AgCl (with saturated KCl solution) as reference electrode.

First, the bare GCE was polished using 0.05 μm alumina powder, sonicated with ultrapure water and ethanol for 1 min, and dried by nitrogen. The as-prepared MOFs were redispersed in a mixture of solvents containing water and Nafion (5%) (v:v = 1:0.008) to form a 1 mg mL⁻¹ solution. Then 10 μL mixture solution of solvents was dropped onto the GCE surface and dried at room temperature, and MOFs modified GCE surface (MOFs/GCE) was obtained. Before experiments, the PBS electrolyte was purged with nitrogen for 15 min to eliminate residential oxygen. Finally, the sensor was tested with optimized condition in 10 mM PBS containing H₂O₂.

Redox characteristics of the electrode interfaces were assessed by cyclic voltammograms (CV) in a 10 mM PBS buffer. The scan rate for the voltammetric measurements was 100 mV s⁻¹. All those CV curves are from the first run of each sample. Amperometric I-t experiment was performed using the modified electrodes with various concentrations of H₂O₂. The potential was kept at -0.55 V and the current versus time was recorded over successive injection of 2 μL aliquots of H₂O₂ in 5 mL 10 mM PBS. The experiment was repeated three times and results are expressed as mean \pm standard deviation.

1.8. Dehydrogenate (DHE) fluorescence

Cellular superoxide generation was detected by DHE staining. Reactive oxygen species (ROS) react with DHE to form ethidium, which then binds to nuclear DNA and releases nuclear fluorescence. Briefly, HepG2 cells were incubated with DHE (1:2000) in the dark for 20 min at 37 °C, and then were rinsed in PBS for ROS detection. A fluorescence microscope was used to observe DHE fluorescence.

1.9. Cytotoxicity tests for QHKUST-1-based sensor

To obtain the cytotoxicity of MOFs-based biosensor, HKUST-1 and QHKUST-1 modified electrodes were immersed into cell culture solution after sanitized with alcohol and short UV light exposure. The cells were dyed using Calcein-AM/PI double-stain kit after 24 h sensor immersion. The cytotoxicity was determined by the fluorescent images of the dyed viable and dead cells obtained a fluorescence microscope.

1.10. Real-time monitoring of H₂O₂ release and drug evaluation

The H9C2 and HeLa cells were grown in 5% CO₂ with the cell culture medium at 37 °C. After growing to 90% confluence, the cells were gently washed with 10 mM PBS for three times. Then, H9C2 and HeLa cells cultured with different concentrations (0.19 and 0.75 μM) of DOX for 24 h were suspended in 10 mM PBS solution, and QHKUST-1/GCE was placed into it for H₂O₂ monitoring. Ascorbic acid (AA) was injected to stimulate cells to produce H₂O₂ and real-time detection of H₂O₂. The amperometric technique was utilized for measuring the current response for H₂O₂ detection by using the modified electrodes.

2. Supplementary Figures and Tables

Table S1 Five types of typical MOFs names and their composition.

Designation	Metal clusters or ions	Organic linkers	Solvent	Conditions	Abbreviation interpretation
HKUST-1	copper nitrate (Cu(NO ₃) ₂)	trimesic acid	methanol	25 °C for 24 h	Hong Kong University of Science and Technology
ZIF-8	zinc nitrate (Zn(NO ₃) ₂)	2-methylimidazole	methanol	25 °C for 24 h	Zeolite Imidazolate Framework
ZIF-67	cobalt nitrate (Co(NO ₃) ₂)	2-methylimidazole	methanol	25 °C for 24 h	Zeolite Imidazolate Framework
MIL-101	iron chloride (FeCl ₃)	benzene-1,4- dicarboxylic acid (H ₂ BDC)	DMF	120 °C for 24 h	Materials of Institut Lavoisier
UIO-66	zirconium chloride (ZrCl ₄)	benzene-1,4- dicarboxylic acid (H ₂ BDC)	DMF	120 °C for 24 h	Universitetet i Oslo
