## 1 Materials and Methods

**Chemicals and Materials:** Platinum Bis(acetylacetonate) ( $\text{Pt}(\text{acac})_2$ , 98%) was purchased from Shanghai Civi Chemical Technology Co., Ltd, ammonium fluoride ( $\text{NH}_4\text{F}$ ,  $\geq 96.0\%$ ) was purchased from Sinopharm Chemical Reagent Co., Ltd, commercial Pt/C catalyst (20 wt%) was purchased from Shanghai Hesen Electric Co., Ltd., oleylamine (OAm), Vulcan XC-72 carbon and Nafion solution (5 wt%) were purchased from Aladdin Industrial Co., Ltd. All reagents and solvents used in experiments were commercially available and were used without further purification. All solutions used in synthesis and electrochemical experiments were prepared with deionized water.

**Synthesis of *in-situ* F-Pt NCs:** In a typical synthesis process,  $\text{Pt}(\text{acac})_2$  (23.7 mg, 0.06 mmol) and  $\text{NH}_4\text{F}$  (203.5 mg, 5.5 mmol) into a glass vial and dissolve in 5 mL OAm. Magnetic stirring for at least 10 h to form a uniform solution (the remaining small amount of  $\text{NH}_4\text{F}$  may not dissolved and does not affect the synthesis process). Subsequently, the glass vial with precursor solution was transferred into a custom pressure-resistant stainless-steel autoclave, which was then filled with  $\text{H}_2$  gas (8 bar). The autoclave was heated from room temperature to 165 °C and kept at a constant temperature for 6 hours with 20 rpm magnetic stirring. After the reaction is over, collected the black colloidal products and washed them with ethanol/chloroform (v/v = 3/1) at least 5 times.

**Synthesis of *in-situ* Pt NCs:** In a typical synthesis process,  $\text{Pt}(\text{acac})_2$  (23.7 mg, 0.06 mmol) into a glass vial and dissolve in 5 mL OAm. Magnetic stirring for at least 10 h to form a uniform solution. Subsequently, the glass vial with precursor solution was transferred into a custom pressure-resistant stainless-steel autoclave, which was then filled with  $\text{H}_2$  gas (8 bar). The autoclave was heated from room temperature to 165 °C and kept at a constant temperature for 6 hours with 20 rpm magnetic stirring. After the reaction is over, collected the black colloidal products and washed them with ethanol/chloroform (v/v = 3/1) at least 5 times.

**Synthesis of *ex-situ* F-Pt/C catalyst:** In a typical synthesis process, commercial Pt/C (25 mg) and  $\text{NH}_4\text{F}$  (203.5 mg, 5.5 mmol) into a glass vial and dissolve in 5 mL OAm. Magnetic stirring for at least 10 h to form a uniform solution (the remaining small amount of  $\text{NH}_4\text{F}$  may not dissolved and does not affect the synthesis process). Subsequently, the glass vial with precursor solution was transferred into a custom pressure-resistant stainless-steel autoclave, which was then filled with  $\text{H}_2$  gas (8 bar). The autoclave was heated from room temperature

to 165 °C and kept at a constant temperature for 6 hours with 20 rpm magnetic stirring. After the reaction is over, collected the black colloidal products and washed them with ethanol/chloroform (v/v = 3/1) at least 5 times.

**Characterizations:** The morphologies were characterized on a transmission electron microscope (TEM, JEM-2100) at 200 kV. High-resolution transmission electron microscope (HRTEM) and high-angle annular dark-field scanning TEM (HAADF-STEM) were collected on a Tecnai G2 F30S-Twin operated at a voltage of 300 kV, and the same equipment was conducted to obtain elemental mapping and energy-dispersive X-ray spectrometry (EDS) result. Powder XRD experiments were performed on a Bruker D2 PHASER diffractometer equipped with a Cu K $\alpha$  radiation ( $\lambda = 1.5406 \text{ \AA}$ ). X-ray photoelectron spectroscopy (XPS) spectra were performed with a Thermo Scientific ESCALAB 250XI system using an Al K $\alpha$  radiation.

**Electrochemical Measurements:** The *in-situ* F-Pt NCs catalyst for the HER was obtained by mixing *in-situ* F-Pt NCs and Vulcan XC-72 carbon. Add 20 wt% of *in-situ* F-Pt NCs and 80 wt% of Vulcan XC-72 carbon into a glass vial. Using cyclohexane as a dispersant, and ultrasound to disperse. After drying, dispersed 5 mg of the catalyst with isopropanol (970  $\mu\text{L}$ ) and 5 wt% Nafion solution (30  $\mu\text{L}$ ), and ultrasonically form the ink. Then 10  $\mu\text{L}$  ink of different catalysts were coated on the surface of L-type glassy carbon electrode (disk diameter, 3 mm; geometric area, 0.07065  $\text{cm}^2$ ) and the loading amount of Pt was 0.14  $\text{mg cm}^{-2}$ . The preparation methods of *in-situ* Pt NCs, commercial Pt/C and *ex-situ* F-Pt/C catalyst are the same as *in-situ* F-Pt NCs catalyst, except that commercial Pt/C and *ex-situ* F-Pt/C do not need to be mixed with carbon black.

All the electrochemical experiments were recorded on CHI-660H workstation (Shanghai Chenhua) with a classic three-electrode system. The L-type glassy carbon electrode coated with catalyst, carbon rod and Hg/HgCl<sub>2</sub> reference electrode were used as working electrode, counter electrode and reference electrode, respectively. The electrolyte was 1 M KOH solution. All potentials were set with the reference of reversible hydrogen electrode (RHE). Linear sweep voltammetry (LSV) was tested with a scan rate of 5  $\text{mV s}^{-1}$ . All the polarization curves were obtained with the 95% ohmic potential drop ( $iR$ ) correction. Stability was evaluated by *i-t* test at near 1  $\text{A cm}^{-2}$  current density.

The electrochemically active surface areas (ECSA) are measured by charge required for underpotentially deposited hydrogen ( $H_{\text{upd}}$ ) and CO stripping. The desorption peaks of  $H_{\text{upd}}$

from recorded CVs were used to calculate the ECSAs, assuming a charge density of  $210 \mu\text{C cm}^{-2}$  for one monolayer of hydrogen coverage on Pt surface. The ECSAs were calculated from the charge of CO stripping (the first CV) by subtracting the background charge (the second CV), assuming a charge density of  $420 \mu\text{C cm}^{-2}$ .<sup>[1, 2]</sup>

**Computational Methods:** All periodic DFT calculations were performed via the Vienna Ab Initio Simulation Package (VASP)<sup>[3, 4]</sup> with gradient-corrected Perdew-Burke-Ernzerhof (PBE) functional<sup>[5]</sup>. The projector augmented wave (PAW) method<sup>[6]</sup> was used to treat interactions between core and valence electrons. The plane wave basis set expansion of valence electrons was cutoff at a kinetic-energy of 400 eV. The optimized lattice parameter of face-centered cubic Pt bulk was 3.967 Å, in good agreement with the reported experimental data of 3.924 Å<sup>[7]</sup>. The Pt(111) surface was modeled by a 5-layer slab with  $3 \times 3$  unit cell. A vacuum gap of 15 Å perpendicular to the surface was added to avoid the interaction between periodic images. The Brillouin zone was sampled by a  $3 \times 3 \times 1$  Monkhorst-Pack k-point mesh<sup>[8]</sup>, which sufficiently converged the adsorption and barrier energies within 0.05 eV<sup>[9]</sup>. For the structure optimizations, adsorbed species and the top three atomic layers were allowed to fully relax, while the bottom two layers were fixed at the bulk positions. A Methfessel-Paxton smearing of 0.1 eV was used to improve the convergence. The energies and forces of relaxations were converged to less than  $10^{-5}$  eV and 0.02 eV/Å, respectively. The geometries were optimized via a conjugate-gradient method, and the transition states between initial and final states were searched by the climbing image nudged elastic band (CI-NEB) method<sup>[10]</sup>. The transition states were further verified by the vibrational frequency analysis with only one imaginary mode. The adsorption energy of pertinent species was computed as,  $E_{\text{ad}} = E_{\text{tot}} - E_{\text{surf}} - E_{\text{mol}}$ , where  $E_{\text{tot}}$  and  $E_{\text{surf}}$  are the energies of the total system and surface with/without F atoms, while  $E_{\text{mol}}$  is the energy of gas H<sub>2</sub>O molecule. A more negative value for adsorption energy indicates a stronger adsorption process. The reaction barrier ( $E_{\text{b}} = E_{\text{TS}} - E_{\text{IS}}$ ) was defined as the energy difference between transition state (TS) and initial state (IS), and the reaction energy ( $\Delta E = E_{\text{FS}} - E_{\text{IS}}$ ) as the energy difference between the final state (FS) and IS.

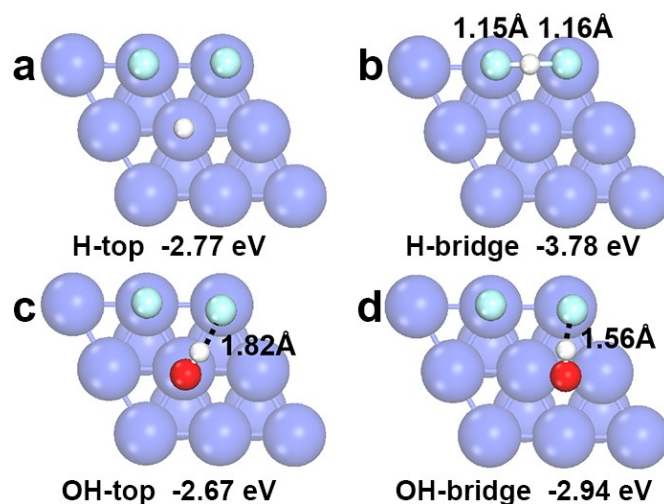

## 2 Supporting Figures

**Figure S1** Optimized geometries of H (a-c), F (d-f), and OH (g-i) adsorbed on Pt(111) surface. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.

**Figure S2** Optimized geometries of H (a-d) and OH (e-f) adsorbed on 1F-Pt(111) surface. The dotted lines label those short distances between H and F atoms in angstrom. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.

**Figure S3** Optimized geometries of H (a-b) and OH (c-d) adsorbed on 2F-Pt(111) surface. The dotted lines label those short distances between H and F atoms in angstrom. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.

**Figure S4** Optimized geometries of H (a-b) and OH (c-d) adsorbed on 3F-Pt(111) surface. The dotted lines label those short distances between H and F atoms in angstrom. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.

**Figure S5** Optimized geometries of H (a-b) and OH (c) adsorbed on 8F-Pt(111) surface. The dotted lines label those short distances between H and F atoms in angstrom. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.

**Figure S6** Optimized geometries of H<sub>2</sub>O on top sites of *n*F-Pt(111) surfaces with *n*=0 (a), 1 (b), 2(c), 3(d), and 8(e). The dotted lines label those short distances between H and F atoms in angstrom. The purple blue, cyan, white, and red spheres represent Pt, F, H, and O atoms, respectively.
