# Unexpected Luminescence of Non-conjugated Biomass-Based Polymers: New Approach in Photothermal Imaging

Felipe de la Cruz-Martínez,<sup>a,‡</sup> Roger Bresolí-Obach,<sup>b,c,‡</sup> Iván Bravo,<sup>d</sup> Carlos Alonso-Moreno,<sup>e</sup> Daniel Hermida-Merino,<sup>f</sup> Johan Hofkens,<sup>b</sup> Agustín Lara-Sánchez,<sup>\*,a</sup> José A. Castro-Osma,<sup>\*,e</sup> Cristina Martín<sup>\*,b,d</sup>

**Abstract:** Population growth, world resources depletion and persistent toxic chemical production underline the need to seek new smart materials from inexpensive, biodegradable, and renewable feedstocks. Hence, “metal-free” ring-opening copolymerization to convert biomass carvone-based monomers into non-conventional luminescent biopolymers is considered a sustainable approach to achieve these goals. The non-conventional emission was studied in terms of steady-state and time-resolved spectroscopy in order to unravel the structure-properties for different carvone-based copolymers. The results highlighted the importance of the final copolymer folding structure as well as its environment in luminescent behavior (cluster-triggered emission). In all cases, their luminescent behavior is sensitive to small temperature fluctuations (where the minimum detected temperature is  $T_m \sim 2$  °C and relative sensitivity is  $S_r \sim 6$  % °C<sup>-1</sup>) even at the microscopic scale, which endows these materials a great potential as thermosensitive smart polymers for photothermal imaging.

### **Materials and methods**

All polymerizations were performed under nitrogen, using standard Schlenk techniques.  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded on a Bruker Ascend TM-500 spectrometer and referenced to the residual deuterated solvent. Gel permeation chromatography (GPC) measurements were performed on a Shimadzu LC-20A instrument equipped with a TSK-GEL G3000H column and a refractive index detector (RID-20A). The GPC column was eluted with THF at 25 °C at 1 mL·min<sup>-1</sup> and was calibrated using eight monodisperse polystyrene standards in the range 580–48300 Da. TGA analysis was performed on a TA instrument TGA-Q50. The heating rate for the sample was 10 °C/min, and the nitrogen flow rate was 60 mL/min. DSC curves were obtained under N<sub>2</sub> atmosphere on a TA Instrument DSC-Q20. Samples were weighed into aluminum crucibles with 5 mg of sample and subjected to two heating cycles at a heating rate of 10 °C/min.

All the solvents used were spectroscopic grade and purchased from Sigma Aldrich. Toluene used for copolymerization processes was predried over sodium wire and distilled under nitrogen from sodium. Deuterated solvents were stored over activated 4 Å molecular sieves and degassed by several freeze-thaw cycles. Carvone-based epoxides were pre-dried over calcium hydride, distilled under vacuum and stored under nitrogen in a glove box. Phthalic and succinic anhydride (Sigma-Aldrich) were sublimed three times and stored under nitrogen in a glove box. All other reagents were purchased from common commercial sources and used as received. The used Au nanospheres suspension with a nominal diameter of 200 nm (EM.GC200) was purchased to BBI solutions (Kent, UK).

**Table S1.** Synthesis of carvone-derived biopolyesters using DMAP as catalyst.<sup>a</sup>

Entry	Anhydride	Epoxide	t (h)	Conv. <sup>b</sup> (%)	TOF (h <sup>-1</sup> ) <sup>c</sup>	Alternating degree <sup>b</sup> (%)	M <sub>n</sub> (kDa) (PDI) <sup>d</sup>
1	PA	COEndo	48	88	0.37	>99	2.76 (1.91)
2	SA	COEndo	48	>99	0.40	>99	2.39 (1.83)
3	PA	COExo	24	92	0.77	>99	3.58 (1.64)
4	SA	COExo	24	>99	0.83	>99	3.12 (1.63)

<sup>a</sup>Reactions were carried out in toluene at 95 °C with a molar ratio DMAP/anhydride/epoxide = 5:100:100. <sup>b</sup>Determined by <sup>1</sup>H NMR spectroscopy. <sup>c</sup>TOF = turnover frequency. <sup>d</sup>Determined by GPC analysis. Conversion of cyclic anhydrides was determined by <sup>1</sup>H NMR spectroscopy by relative integration of protons in PA (CDCl<sub>3</sub>, δ = 7.8-8.0 ppm) or SA (CDCl<sub>3</sub>, δ = 2.9 ppm) and poly(PA-*alt*-COEndo) (CDCl<sub>3</sub>, δ = 7.5-7.8 ppm), poly(SA-*alt*-COEndo) (CDCl<sub>3</sub>, δ = 2.5-2.8 ppm) or poly(PA-*alt*-COExo) (CDCl<sub>3</sub>, δ = 7.4-7.8 ppm), poly(SA-*alt*-COExo) (CDCl<sub>3</sub>, δ = 2.5-2.8 ppm).

The renewable carvone-derived polyesters were synthesized by ROCOP of phthalic or succinic anhydrides and carvone-based epoxides using DMAP as catalyst (Table 1). Reactions were carried out in toluene at 95°C with a molar ratio 5:100:100 of DMAP, cyclic anhydride and epoxide. When carvone-derived *endo*-epoxide (COEndo) was used as monomer, copolymerizations required a longer time, which is attributable to the lower reactivity of tri-substituted epoxides compared with *gem*-di-substituted analogues (Table 1). On the other hand, ROCOP proceeded efficiently, and excellent conversions were obtained when succinic anhydride was used as substrate (Table 1, entries 2 and 4).
