**Scheme S1** UC-NC synthetic process.

**Figure S1** ATR-IR Spectrum of upconverting nanocapsules.

**Figure S2** UV-Vis absorption spectrum (in Kubelka-Munk units) of upconverting nanocapsules.

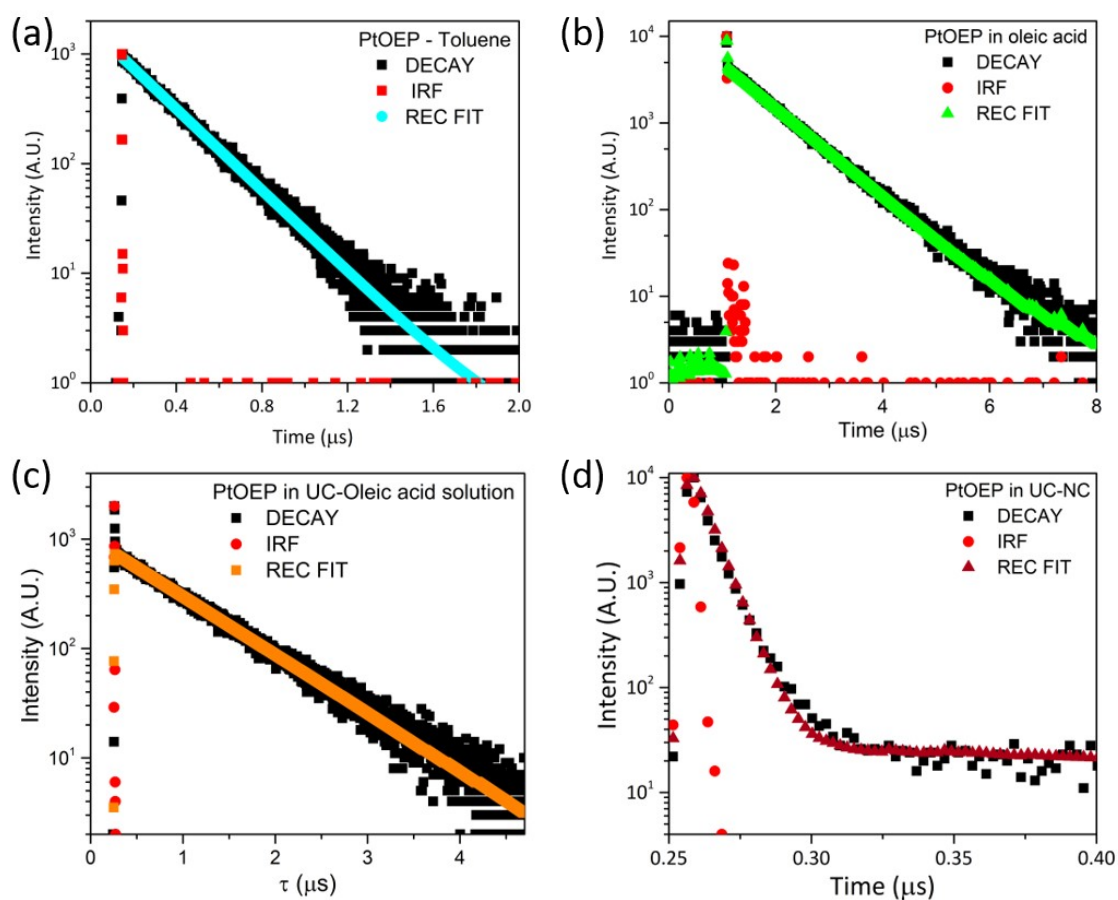

**Figure S3.** EDX mapping and spectra of upconverting nanocapsules.

### Characterization of PtOEP/DPA in oleic acid solution

UC- emission spectrum of PtOEP/DPA in oleic acid has been measure and monitored as a function of the excitation power (Figure S3), generated by a 450 W xenon lamp. The sample was not previous deoxygenated.

**Figure S4** a) upconversion emission of PtOEP-DPA system in oleic acid solution. b) upconversion quantum yield vs excitation power density plot for PtOEP-DPA system in oleic acid solution.

**Figure S5** Phosphorescence decays of PtOEP in toluene (a), oleic acid (b); Phosphorescence decays of PtOEP in the presence of DPA in oleic acid solution (c) and in UC-NC solid-like powder (d) registered in aerated conditions.

**Table S1** Luminescence decays parameters of PtOEP in toluene, oleic acid in the absence and in the presence of DPA and in UC-NC.

$\lambda_{\text{exc}} - \lambda_{\text{em}}$ (nm)	Detected emission	Average Decay From MEM distributions
510 nm – 645 nm	PtOEP in toluene	$\tau_1 = 75.2$ ns $\tau_2 = 235$ ns
510 nm – 645 nm	PtOEP in OA solution	$\tau_1 = 410$ ns $\tau_2 = 1.01$ $\mu$ s
510 nm – 645 nm	PtOEP in UC-OA solution (with DPA)	$\tau_1 = 2.35$ ns $\tau_2 = 818.6$ ns
510 nm – 645 nm	PtOEP in UC-NC (with DPA)	$\tau_1 = 1.8$ ns $\tau_2 = 6.8$ ns

**Figure S6** MEM analysis of PtOEP in toluene (a) and oleic acid (b) in absence of DPA and in solid-like powder UC-NC (c).

**Table S2** Fuzzy Entropy (H) values determined for the different samples in different excitation conditions.

Sample	$\lambda_{\text{exc}}$ (nm) [Excitation condition]	Fuzzy Entropy (H)
DPA in OA	[direct]	0.11
DPA in UC-NC	[direct]	0.29
PtOEP in Toluene	[direct]	0.19

PtOEP in OA	[direct]	0.21
PtOEP in UC-NC	[direct]	0.27
UC signal by DPA	[UC]	0.59

**Figure S7** Phosphorescence spectra of PtOEP in toluene (A) and oleic acid (B) solution, and UC-NC (C) registered at different intervals of time of  $O_2$  flow. Insert: Plot of  $I_0/I$  as a function of oxygen flow time.

## Mechanism of the Belousov-Zhabotinsky (BZ) reaction

The BZ reaction is a catalysed oxidative bromination of malonic acid, which occurs according to the following equation:

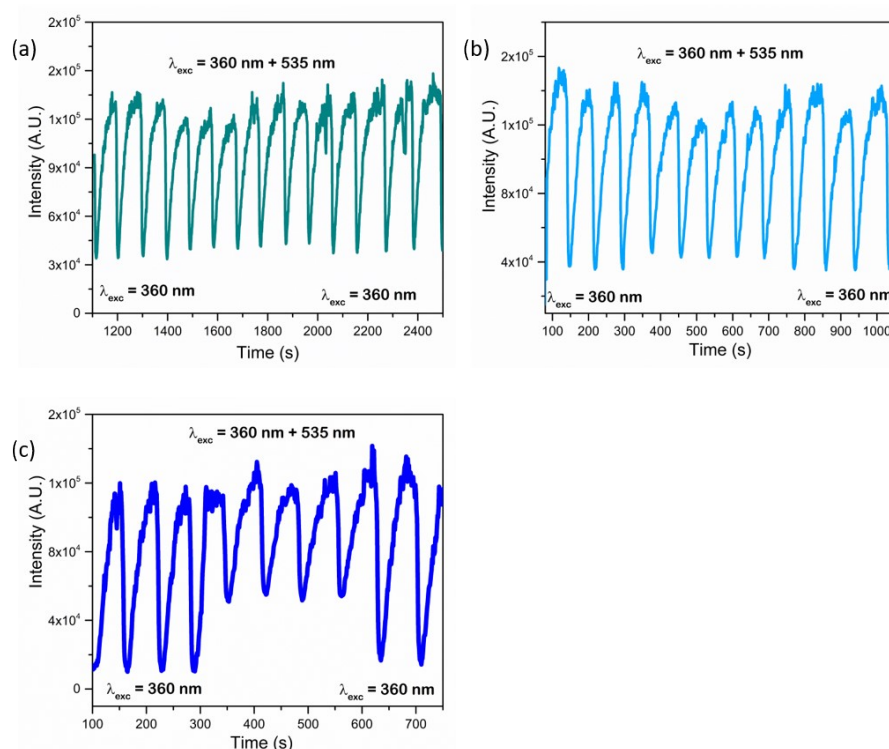

The mechanism of the BZ reaction, catalysed by cerium ions, consists of many elementary steps, which be grouped into three sets of chemical transformations:<sup>1,2</sup>

- 1) The first set consists in non-radical reactions, wherein the overall effect is the consumption of Br<sup>-</sup> and the production of BrCH(COOH)<sub>2</sub>. This step is relevant when the concentration of Br<sup>-</sup> is high (above the critical value of  $5 \times 10^{-6}$  [BrO<sub>3</sub><sup>-</sup>]) and the catalyst is in its reduced state (Ce(III)).
- 2) The second set of elementary steps consists in mono-electronic redox reactions, that occur when the Br<sup>-</sup> concentration is driven below its critical value and the autocatalyst bromous acid becomes the main character. In this stage, Ce(IV) is produced.
- 3) To restore the Ce(III) state, a new set of reactions needs to occur: the bromomalonic acid is oxidized up to CO<sub>2</sub> and H<sub>2</sub>O, consuming Ce(IV) and producing again Br<sup>-</sup>. When [Br<sup>-</sup>] becomes higher than its critical value (i.e., above  $5 \times 10^{-6}$  [BrO<sub>3</sub><sup>-</sup>]), the first set of elementary steps restarts again.

**Figure S8** Transmittance evolution spectra and kinetic profile (insert) of the optical density of Belousov-Zhabotinsky solution.

**Figure S9** Intensity of signals at 430 nm Vs irradiation time upon excitation at 360 nm (0-1800 s) and 535 nm (between 600 s and 1200 s) with a power density of 55  $\mu\text{W}/\text{cm}^2$ . Power density at 360 nm of 13 (A) 6 (B) 1 (C)  $\mu\text{W}/\text{cm}^2$ .

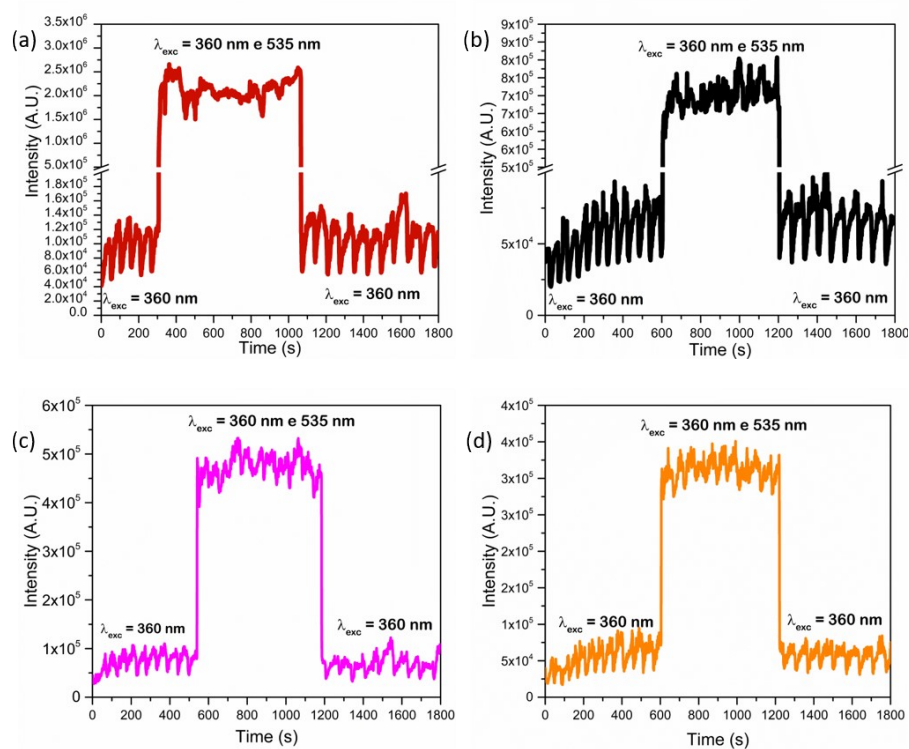

**Table S3** Amplitude variation of the output signal of DPA in presence of a double excitation (360 nm + 535 nm), referred to the amplitude of the same signal obtained with a single input (360 nm).

360 nm Power excitation ( $\mu\text{W}/\text{cm}^2$ )	$\Delta$ -Amplitude ( $I_{360 \text{ nm}} - I_{360 \text{ nm} + 535 \text{ nm}} / I_{360 \text{ nm}}$ )
13	0.08
6	0.13
1	0.37

**Scheme S2** Amplitude of the output signal of DPA in presence of single (360 nm, in green) and simultaneous excitation (360 nm plus 535 nm, in red).

**Figure S10** Intensity of signals at 645 nm Vs irradiation time upon excitation at 360 nm (0-1800 s) and 535 nm (between 600 s and 1200 s) with a power density  $133\mu\text{W}/\text{cm}^2$ ; power density at 535 nm of  $55\mu\text{W}/\text{cm}^2$  (A),  $11\mu\text{W}/\text{cm}^2$  (B)  $5.5\mu\text{W}/\text{cm}^2$  (C)  $2.8\mu\text{W}/\text{cm}^2$  (D).
