## EXPERIMENTAL SECTION

**Materials and synthesis.** New phosphor samples with nominal composition of  $\text{LaZn}_{1-x}\text{Al}_{11}\text{O}_{19}: x\text{Mn}^{2+}$  ( $x = 0 - 0.4$ ) were prepared via solid-state reaction method at  $1600^\circ\text{C}$  for 4 hours under 85%  $\text{N}_2$ +15%  $\text{H}_2$  reductive atmosphere by using the starting reagents:  $\text{La}_2\text{O}_3$ ,  $\text{ZnO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$  and  $\text{MnCO}_3$  (A.R.) powders.

The PiG sample was prepared by co-sintering  $\text{LaZn}_{1-x}\text{Al}_{11}\text{O}_{19}: x\text{Mn}^{2+}$  phosphor particles and the  $\text{TeO}_2$ - $\text{B}_2\text{O}_3$ - $\text{ZnO}$ - $\text{Na}_2\text{O}$  low-melting glass via a two-step melt-quenching method. Precursor glasses were prepared by a conventional melting-quenching method. The reagent grade chemicals were mixed thoroughly and melted in a platinum crucible at  $750^\circ\text{C}$  for 0.5 h in ambient atmosphere. Then, the melt was poured into a cold copper mold and then cooled to room temperature. The prepared glass was milled to powders using a ball grinder, and then mixed with the  $\text{La}(\text{Zn},\text{Mn})\text{Al}_{11}\text{O}_{19}$  phosphors thoroughly and sintered in a platinum crucible at  $540^\circ\text{C}$  for 20 min in ambient atmosphere.<sup>1-2</sup> As a proof-of-concept experiment, the remote-type NIR-LED was constructed by encapsulating a stacking PiG plate on the commercial blue chip ( $\text{InGaN}$ ~ 450 nm). The PiG color converter was horizontally fastened on the blue chip, with opaque silica gel coated around the edge to prevent leakage of blue light.

**Characterization.** The powder X-ray diffraction (PXRD) patterns of the as-obtained samples were collected on a X' Pert PRO diffractometer ( $\text{Cu K}\alpha$  radiation,  $\lambda = 1.5406 \text{ \AA}$ ) at 298 K. The microstructure was analyzed using a scanning electron microscope (SEM, JSM-6700F). The X-ray photoelectron spectroscopy (XPS, Thermo

fisher Scientific K-Alpha) was conducted to identify the chemical states of the elements in the sample. A FLS-980 fluorescence spectrophotometer (Xe 900, 450 W arc lamps) was employed to obtain the photoluminescence (PL), photoluminescence excitation (PLE), and decay curve spectra. An absolute photoluminescence quantum yield measurement system (Hamamatsu, Quantaaurus-QY plus C13534-31) was adopted to test the quantum efficiency. The photoelectric performance of the obtained w-LED device was measured in an integrating sphere of 50 cm diameter, which was connected to a CCD detector with an optical fiber (ATA 100, Everfine).

**Computational methods.** Utilizing density functional theory (DFT) as implemented in the Vienna *ab-initio* simulation package code,<sup>3</sup> we investigate the electronic structures of title compound. We used projector augmented wave (PAW) method<sup>4</sup> for the ionic cores and the generalized gradient approximation (GGA) for the exchange-correlation potential, in which the Perdew-Burke-Ernzerhof (PBE) type<sup>5</sup> exchange-correlation was adopted. The reciprocal space was sampled with  $0.03 \text{ \AA}^{-1}$  spacing in the Monkhorst-Pack scheme for structure optimization, while denser k-point grids with  $0.01 \text{ \AA}^{-1}$  spacing were adopted for properties calculation. We used a mesh cutoff energy of 400 eV to determine the self-consistent charge density. All geometries are relaxed until the Hellmann-Feynman force on atoms is less than  $0.01 \text{ eV/\AA}$  and the total energy change is less than  $1.0 \times 10^{-5} \text{ eV}$ . The calculation models were built from the crystal structure.
