## 1. General Information

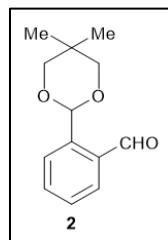

All reported NMR spectra ( $^1\text{H}$ ,  $^{13}\text{C}$  and  $^{19}\text{F}$  NMR) were recorded using a Varian 500 and 600 or Bruker 500 spectrometers. Chemical shifts ( $\delta$  ppm) were determined with TMS as the internal reference,  $J$  values are given in Hz. The  $^1\text{H}$  NMR spectrum of pure deuterated THF (page 27) shows additional signals at around 2.5 and 11 ppm, which are observed in some NMR spectra registered in THF- $d_8$ . High resolution mass spectra (HRMS) were obtained via electron ionization (EI) source and an EBE double focusing geometry mass analyzer or spectrometer equipped with electrospray ion source with q-TOF type mass analyzer (ESI) or by atmospheric pressure chemical ionization (APCI). Chromatography was performed on silica gel 60 (230-400 mesh) and thin layer chromatography was performed on TLC plates (Merck, silica gel 60 F<sub>254</sub>).

## 2. Synthesis

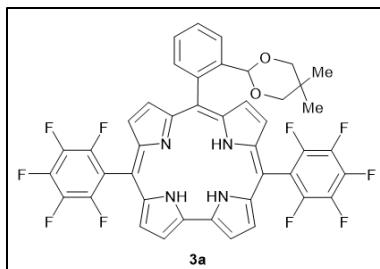

**Scheme S1.** Synthesis of 2-(5,5-dimethyl-1,3-dioxan-2-yl)benzaldehyde (**2**).

**Synthesis of 2-(5,5-dimethyl-1,3-dioxan-2-yl)benzaldehyde (**2**).** Round bottom flask was charged with phthalaldehyde (5.45 g, 41.0 mmol), 2,2-dimethylpropane-1,3-diol (4.25 g, 41.0 mmol) and  $p\text{-TsOH}$  (0.025 g, 0.15 mmol). Following next, toluene was added (60 ml) and the reaction mixture was stirred at  $130\text{ }^\circ\text{C}$  (oil bath) for 3 h with Dean-Stark trap. After this time, the mixture was cooled to room temperature and the solvent was evaporated. Crude product was purified by column chromatography (silica, hexane/ethyl acetate 4:1) to afford product of analytical purity.

Single crystal X-ray diffraction measurements were carried out on a Rigaku SuperNova diffractometer, at 100 K with Cu K $\alpha$  radiation (1.54184 Å). Violet crystal of approximate dimensions of 0.1 x 0.04 x 0.03 mm (block) was used. The structures were solved by direct methods and refined on F<sup>2</sup> by full-matrix least-squares. All non-hydrogen atoms were refined as anisotropic while hydrogen atoms were placed in calculated positions, and refined in riding mode.

#### 4. Experimental Methods

Spectroscopic grade solvents were purchased from Sigma-Aldrich and used as obtained. For optical studies solutions of molecules at low concentrations, about few micromoles per liter, were used to avoid dimerization or reabsorption effects. All absorption and fluorescence spectra were taken at room temperature (21 °C). A Perkin Elmer UV/VIS Spectrometer model Lambda 35 was used for absorption spectra measurement. Fluorescence spectra were recorded with the FLS 1000 Spectrofluorometer from Edinburgh Instruments and corrected for the spectral response sensitivity of the photodetector. Fluorescence quantum yields (FQY) of molecules in solvents at 21 °C were determined using an integrating sphere. Molar absorptivity (absorption coefficient),  $\varepsilon$  was calculated from absorbance,  $A$ , of solution of given molar concentration,  $c$ , in cuvette of length,  $l$ , with a well-known formula  $A=c \cdot \varepsilon \cdot l$ .

## 6. Computational Results

True minima for **4a** and **6a** have been determined using Gaussian16 at the B972/6-31G(d) level, using the SMD solvent to model the solvent (chloroform for **6a** and THF for **4a**).

The optimized geometry of **4a** turns out similar to the X-ray crystal structure.

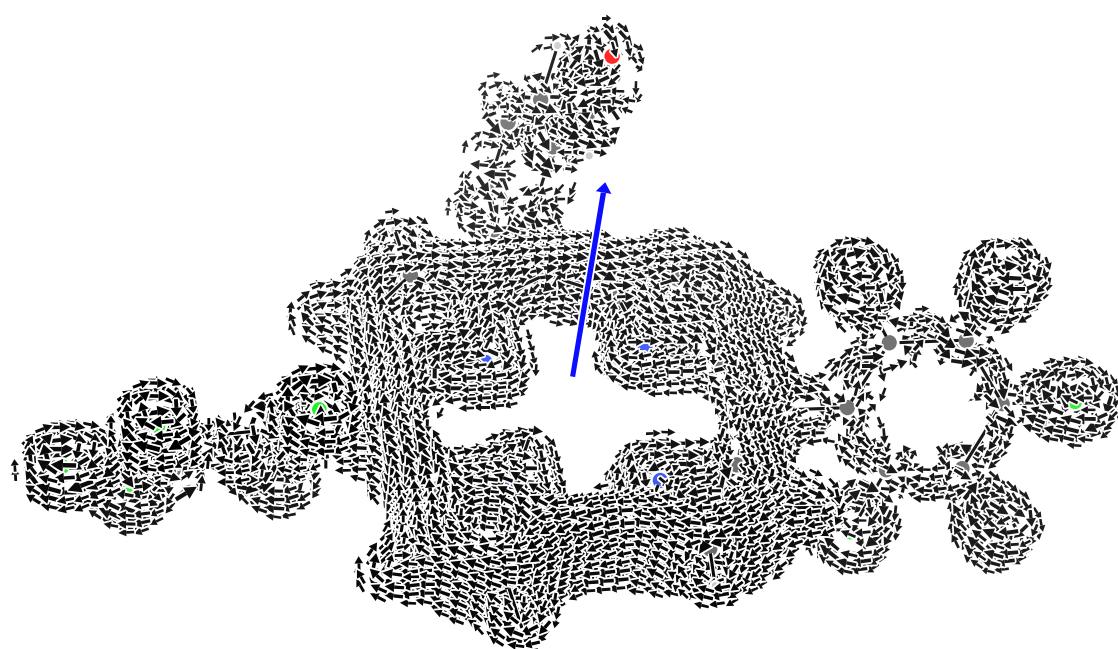

The calculation of the magnetic response has been done still with the SMD model and the appropriate solvent, but at the B972/6-311+G(2d,p) level, and using the CSGT method<sup>S1</sup> to distribute the origin, according to the Gaussian16 keywords NMR=CSGT output=(csgt,wfx).

The \*.wfx file was then used in SYSMOIC to compute the current density and the current strengths, according to the CTOCD-DZ2 method.<sup>S2-S3</sup> Selected results are reported in Figs. S5-S8 and Table S3-S4.

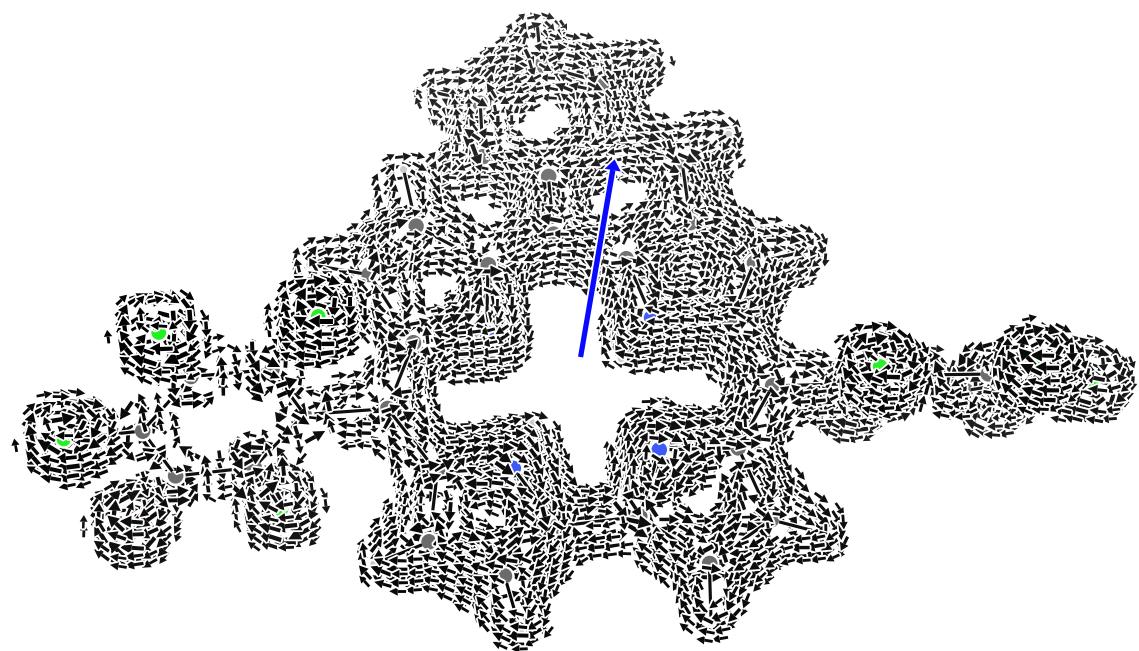

Isotropic nuclear shieldings, which can be obtained by integration of the current density and are an indirect indication of its quality, are reported in Table S3, together with the computed chemical shifts, obtained as  $\delta_{\text{calc}} = A + B \sigma_{\text{iso}}$ , where the values  $A=31.29(5)$  ppm and  $B=-0.974(5)$  have been determined by least squares refinement of  $\sigma_{\text{iso}}$  vs  $\delta_{\text{exp.}}$  ( $R^2=0.9996$ ), in analogy with ref. S4.

**Table S3.** Computed isotropic proton nuclear shieldings and chemical shifts for **4a**. All entries in ppm, but for the numbers of the proton, consistent with Cartesian coordinates, reported below.

a) Values of  $\overline{I\%}$  have been obtained from Fig. 3 and Fig. S5 averaging over bonds that should have the same current according to the current conservation.

b) For non-planar molecules the  $\sigma/\pi$  separation cannot be clear cut. A set of 23 and 24 orbitals has been selected for **4a** and **6a**, respectively, combining visual inspection and the low density value at the nuclei and at bond midpoints. Orbitals numbers are 180, 179, 178, 177, 176, 175, 174, 173, 172, 171, 170, 169, 167, 165, 164, 161, 158, 133, 131, 127, 126, 125, 124 for **4a**, 115, 116, 121, 122, 124, 127, 129, 130, 131, 165, 169, 170, 171, 173, 174, 175, 176, 177, 178, 179, 180, 183, 184, 185 for **6a**.

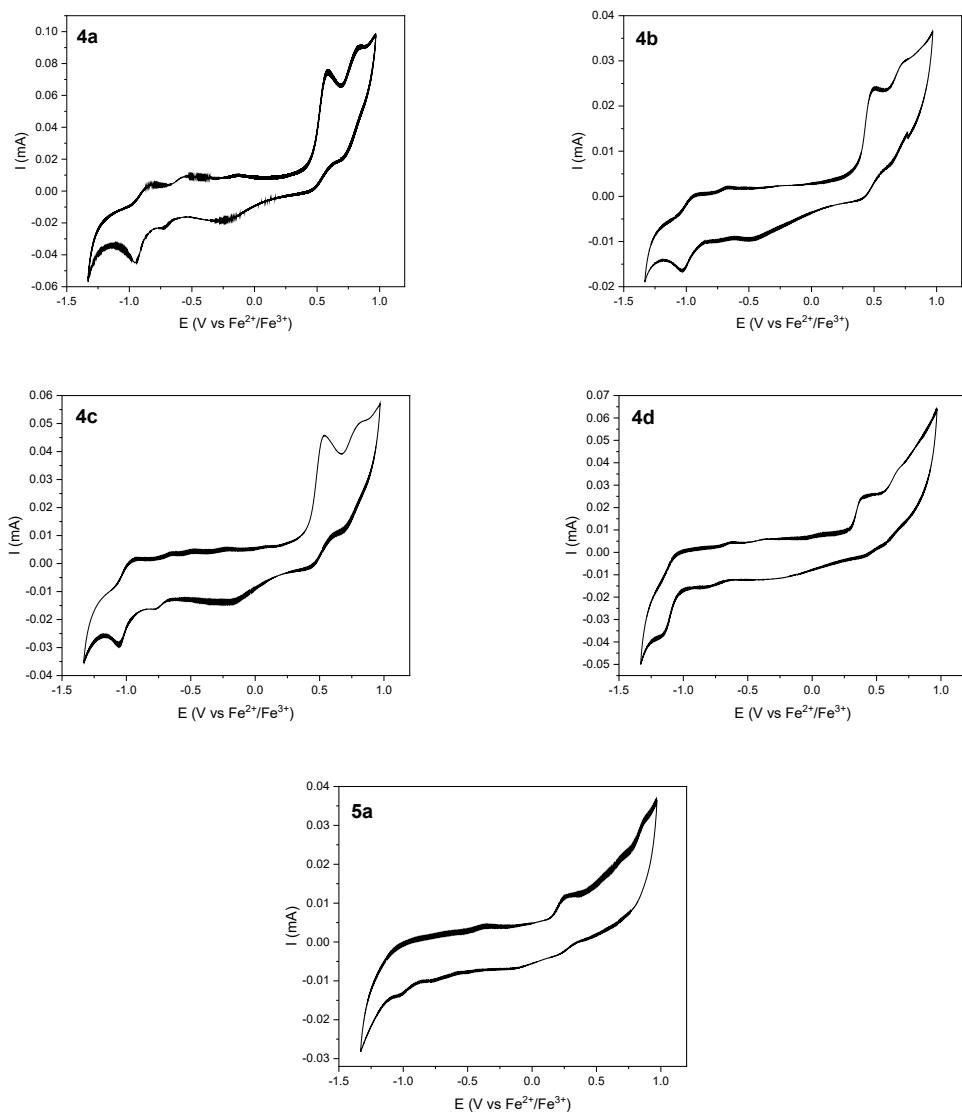

c) The magnetic shielding tensor  $\sigma_R$  at 1 Å above the average plane of ring R has been obtained by integration of the current density. Then the NICS <sub>$zz$</sub>  of ring R has been computed as  $\text{NICS}_{zz}^R = -\mathbf{n}^T \sigma_R \mathbf{n}$ , where  $\mathbf{n}$  is the unit column vector perpendicular to the average plane of ring R and T indicates transposition.

d) The HOMA of the macrocycle has been computed either following the outer path (the first entry) or the inner path passing through the 4 N atoms (value in parentheses).

## 7. Electrochemical Data

All compounds were tested in 0.1 M Tetrabutylammonium tetrafluoroborate (TBABF<sub>4</sub>)/Benzonitrile solution (50 mM). The electrochemical measurements were performed with Bio-Logic VSP potentiostat. Cyclic voltammetry (CV) was conducted at scan rate of 100 mV/s under inert atmosphere. A 3-electrodes cell was placed in a sealed box and washed for an hour with Ar. Ar was bubbled into the solution 2 mins before the measurement. The working, counter, and pseudo-reference electrodes were Pt wire, glassy carbon rod and Ag wire, respectively. The reference potential was calibrated against ferrocene/ferrocenium redox couple by adding a small amount of ferrocene to the tested solution after the experiments. All potentials are reported vs. Fc/Fc<sup>+</sup>.

**Spectroelectrochemistry:** Since these compounds have nonaromatic character, they are expected to have fast and complicated electron transitions, and the shifts in the absorption spectra were relatively small. The most significant changes were found at the split Soret peaks of compounds **4a** and **4d**. This split peak can be deconvoluted into two main peaks with maxima at 432.4 nm and 451.0 nm for **4a** and, 426.2 nm and 442.9 nm for **4b**. Upon increasing the applied potential from beyond the reduction peak (in the CV), towards higher potentials, there is decrease in the intensity of the Soret peak located at the higher wavelength in parallel to increase in the intensity of the lower one.

**Figure S9.** Cyclic voltammograms for compounds **4a-d** and **5a**.

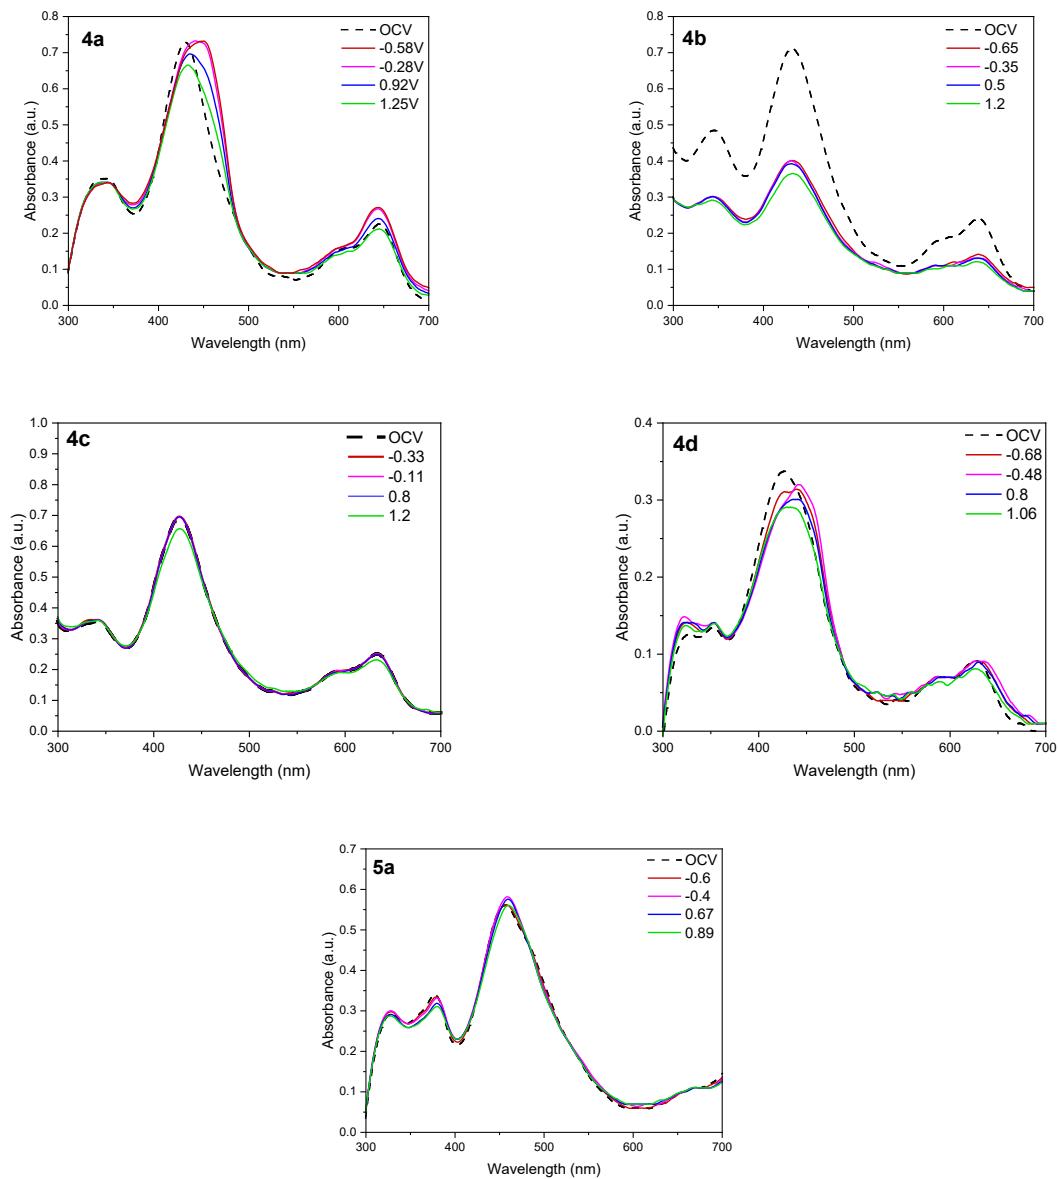

**Table S5.** HOMO-LUMO energy values for compounds **4a-d** and **5a**.

The HOMO-LUMO energy gap was calculated from the difference between E<sub>HOMO</sub> to E<sub>LUMO</sub>.<sup>S8</sup>
