**Experimental section**

Materials: All reagents mentioned were obtained directly without further processing:

Iridium trichloride(IrCl$_3$, 99%) was supplied by Shanxi KaiDa chemical engineering Co., Ltd. Polyvinyl-pyrrolidone(PVP, K29~K32, Average Mw~58000) was purchased directly from MACKLIN reagent Company, Citric acid (CA, 99%), Nickel chloride(NiCl$_2$, 98%), benzyl alcohol (C$_7$H$_8$O, 99%) and glyoxal (C$_2$H$_2$O$_2$, 99%) were all obtained from Sinopharm reagents. Deionized water used in the experiment (resistivity ≥ 18.25 MΩ) was obtained from ULUPURE.

Synthesis of Ir-ENS and NiIr-ENS: The samples in the experiment were obtained by a one-step liquid-phase reduction method. Firstly, IrCl$_3$ (7.5 mg), PVP (100 mg), CA (48 mg) were weighed and transferred to benzyl alcohol (6 mL) containing glyoxal (0.2 mL) at room temperature with a stirring rate of 1000 rpm s$^{-1}$ for more than 30 min and then transferred to an autoclave of polytetrafluoroethylene (10 mL), which was heated up from room temperature to 200 °C within 60 min and held for 5 h. Ir-NS was obtained by centrifugation after cooling to room temperature and washing with a mixture of ethanol and water (3/7 vol.) for more than 3 times. The preparation method of NiIr-ENS is identical to that of Ir-ENS, except for the addition of NiCl$_2$ (3 mg) as a precursor. In particular, the XRD and XPS project tests were characterized by mixing the obtained sample with carbon black (XC72).

Fundamental characterizations: Material surface morphology and crystal structure were obtained by field emission scanning electron microscopy (SEM, Hitachi-
SU8010) and transmission electron microscopy (TEM, Thermo Fisher Scientific F200x, United States). The physical phases of the electrocatalysts synthesized by X-ray diffraction (XRD, Bruker AXS D8-Focus, Germany) in the range of 5-90° were examined using Cu-Kα radiation. X-ray photoelectron spectroscopy (XPS) was performed using Thermo-Scientific K-α equipment.

Electrochemical measurements: Ink was obtained by ultrasonicating the freshly synthesized catalyst (2 mg) and carbon black (2 mg) dispersed in solution (780 μL deionized water, 200 μL isopropanol and 20 μL Nafion (5 wt%)) for more than 0.5 h. The 10 μL of ink was coated on a glassy carbon electrode (GCE, d=3 mm) to obtain a working electrode, and electrochemical tests were performed at room temperature (25 °C) using a Gamry (Interface 1000E, USA) equipment using a three-electrode system (a carbon rod as the counter electrode and an Hg/HgCl as the reference electrode). The 0.5 M H₂SO₄ solution was used for the electrochemical electrolyte and the solutions were saturated with N₂ for 30 min prior to the HER or overall water-splitting test or with O₂ prior to the OER test. The linear sweep voltammetry (LSV) curves were recorded with a scan rate of 5 mV s⁻¹, Cyclic Voltammetry (CV) was carried out with a scan rate of 50 mV s⁻¹. The electrochemical double-layer capacitance was measured at different scan rates from 10 to 100 mV s⁻¹, EIS was measured from 100 kHz to 0.01 Hz under AC voltage amplitude of 5 mV and DC voltage based at a given potential at 10 mA cm⁻². The long-term stability was measured by chronoamperometric (i-t) stability examination at a given potential. A two-electrode system for the water-splitting with the catalysts loading of 0.285 mg cm⁻² onto GCE
and used as both the anode and cathode. All potential were converted to the reversible hydrogen electrode (RHE) based on the equation: $E_{\text{RHE}} = E_{\text{Hg/HgCl}} + 0.241 + 0.0591 \cdot \text{pH}$.

DFT calculations: All DFT calculations were performed using Vienna Ab Initio Simulation Package (VASP) in a spin-polarized mode. The exchange–correlation effect was estimated by Generalized Gradient Approximation Perdew–Burke–Ernzerhof (GGA-PBE) functionals. A plane wave basis with a cut off energy of 550 eV was used to expand the Kohn-Sham wave functions. Convergence criteria for geometry structures were set to be that residual energy and force were below $10^{-5}$ eV and -0.02 eV/Å respectively. A $3 \times 3 \times 1$ gamma centered k-point grid was used to sample (111) surfaces. The top two layers of the surfaces were fully relaxed during structural optimization.

The energy ($E_{\text{ads}}$) of each primitive step is defined as:

$$\Delta G_{\text{ads}} = \Delta E_{\text{DFT}} + \Delta E_{\text{ZPE}} + T^* \Delta S$$

among $\Delta E_{\text{DFT}}$ is the binding energy obtained by DFT, and the zero-energy correction difference $\Delta E_{\text{ZPE}}$ and $T^* \Delta S$ is calculated by vibration analysis.
Table S1 Comparison of electrochemical performance of Ir-based electrocatalysts tested in acidic electrolyte.
