Experimental

Materials and chemicals

Sodium hypophosphite (NaH_2PO_2), iridium chloride hydrate ($\text{IrCl}_3 \cdot x\text{H}_2\text{O}$, 99.9%), formic acid (HCOOH , 88%) and Sulfuric acid (H_2SO_4 , 95%~98%) were purchased from Aladdin. Trimethylstearylammomium chloride (OTAC, 98.0%) was obtained from Tokyo Chemical Industry Co. Ltd. Nafion (5wt%) were obtained from Sigma-Aldrich. Commercial Pt/C (20wt%) was purchased from Alfa Aesar.

Synthesis of P-Ir metallene

Ir metallene was first synthesized through a wet chemical reduction method. Typically, 8.0 mg of OTAC was dissolved in 1.0 mL of IrCl_3 (40 mM) and 2.0 mL of deionized water under continuous sonication for 10 min, followed by adding 1.0 mL of HCOOH . Then, the mixture solution was reacted at 95 °C for 4 h. After that, dark grey products were collected by centrifugation and washing for six cycles. For phosphorus doping, 10 mg Ir metallene and 100 mg NaH_2PO_2 was placed in a quartz boat, heating to 300 °C under N_2 atmosphere with heating rate of 2 °C min^{-1} and reacting for 2 h. Finally, the dark grey products were collected after washing. For comparison, we synthesized P-Ir-L metallene and P-Ir-H metallene from different amounts of NaH_2PO_2 under similar conditions (50 and 200 mg), respectively.

Characterizations

Transmission electron microscopy (TEM, TalosS-FEG) equipped with energy dispersive X-ray spectroscopy (EDX) was used to characterize morphology and microstructure of samples. The crystalline of catalysts was analyzed by X-ray powder diffraction (XRD, Ultima IV, Rigaku, Japan).

X-ray photoelectron spectroscopy (XPS, K-Alpha) was used to analyze surface elemental composition and electronic structure of catalysts.

Electrochemical measurements

HER and OER Measurements were performed by CHI660E instrument using conventional three-electrode system in 0.5 M H₂SO₄, in which catalyst-coated glassy carbon electrode (GCE, 0.071 cm²) as working electrode, Ag/AgCl (3M KCl) electrode as reference electrode and carbon rod as counter electrode. The obtained P-Ir metallene was ultrasonically dispersed in water to form homogeneous catalyst ink (2 mg mL⁻¹). Prior to each measurement, catalyst ink (5 µL) was coated on polished GCE, followed by adding 3.0 µL of Nafion (0.05 wt%) to the surface to prepare the working electrode. Linear sweep voltammetry (LSV) was performed at 1 mV s⁻¹. Electrochemical impedance spectroscopy (EIS) measurements were carried out in 0.5 M H₂SO₄ at -0.28 V in frequency range of 0.1 Hz and 100 kHz with an amplitude of 5 mV. All potentials were converted to reversible hydrogen electrode (RHE) according to the equation E (RHE) = E (Ag/AgCl) + 0.2224 V + 0.05916×pH. Overall water splitting was carried out in two-electrode cell under 0.5 M H₂SO₄ using catalyst-dispersed carbon paper as both anode and cathode (1 mg cm⁻²).
