## 1. Experimental Procedures

General Procedures and Materials: All operations were performed in a Mbraun glovebox under an $\mathrm{N}_{2}$ atmosphere. Solvents were dried using a J. C. Meyer solvent system, degassed by free-pump-thaw method and stored over activated $4 \AA$ molecular sieves prior to use. The 1,2,4,5-tetrazine (tz) ligand was prepared according to the literature. ${ }^{[1]}\left[\mathrm{Cp}{ }_{2}{ }_{2} \mathrm{~Tb}\right]\left[\left(\mu-\mathrm{Ph}_{2}\right) \mathrm{BPh} 2\right]$ starting material was prepared according to the literature. ${ }^{[2]}$ All reagents and solvents were purchased from TCI, Alfa Aesar, or Strem Chemicals and used without further purification. HCp* (99+\%) was purchased from Alfa Aesar and was degassed/dried as previously described prior to use. The FT-IR sample was prepared under inert conditions between NaCl plates and the spectra recorded on a Nicolet Nexus 550 FT-IR spectrometer in the transmission window of $400-4000 \mathrm{~cm}^{-1}$. Elemental Analysis was performed by Midwest Microlab.

Synthesis of $\left[\left(\mathbf{C p}^{*}{ }_{2} \mathbf{T b}\right)_{4}\left(\mathrm{tz}^{*}\right)_{4}\right] \cdot \mathbf{3}\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)(\mathbf{1})$ : A solution of tz $(0.125 \mathrm{mmol}, 10 \mathrm{mg})$ and $\mathrm{KC}_{8}(0.125 \mathrm{mmol}, 17 \mathrm{mg})$ in benzene ( 6 mL ) was added to a solution of $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{~Tb}\right]\left[\left(\mu-\mathrm{Ph}_{2}\right) \mathrm{BPh}_{2}\right](0.125 \mathrm{mmol}, 93 \mathrm{mg})$ in benzene $(3 \mathrm{~mL})$ to afford a dark red slurry. The mixture was stirred overnight, filtrated, and left undisturbed at room temperature. After several weeks dark red prismatic crystals of 1 suitable for single crystal X-ray were obtained in $32 \%$ yield. IR ( $\mathrm{cm}^{-1}$ ): 3034.29 ( w ), 2970.52 (w), 2899.25 (s), 2855.29 (s), 2721.82 (w), 1827.86 (w), 1529.29 (w), 1478.86 (m), 1427.74 (vs), 1375.81 (m), 1255.21 (m), 1223.89 (vs), 1179.56 (s), 1096.33 (s), 1096.33 (s), 1060.93 (m), 1019.20 (s), 905.98 (m), $891.19(\mathrm{~s}), 857.32$ (w), 804.31 (w), 681.73 (vs), 593.55 (m), $555.20(\mathrm{w}), 535.89(\mathrm{~m}), 538.57$ (m). Elemental Anal. Calcd: C, $55.84 \%, \mathrm{H}, 6.45 \%, \mathrm{~N}, 9.83 \%$, Found: C, $56.07 \%, \mathrm{H}, 6.42 \%, \mathrm{~N}, 9.78 \%$.

Single Crystal X-ray Diffraction: Suitable crystals for single-crystal X-ray diffraction (SCXRD) analysis were covered in parabar oil and mounted on a cryoloop. Full data (Table S1) were collected on a Bruker KAPPA APEX-II CCD single-crystal diffractometer (graphite monochromated Mo-Ka radiation, $\lambda=0.71073 \AA$ ), at 203 K temperature. Absorption corrections were applied by using multi-scan of the SADABS ${ }^{[3]}$ program. The structure was solved using direct methods with SheIXT ${ }^{[4]}$ structure solution program and refined by the full-matrix least-squares methods on $F^{2}$ with ShelXL ${ }^{[5]}$ refinement package. All non-H atoms were refined by full-matrix least-squares with anisotropic displacement parameters. All H atoms were generated geometrically and were included in the refinement in the riding model approximation. The temperature factors of all H atoms were set to multiple of the equivalent isotropic temperature factors of the parent site (aromatic 1.2 times; methyl 1.5 times the factor). In $\mathbf{1}$, there is a positional disorder on all ligands and cocrystallized benzene solvent molecules. After careful refinement, the ratio was found to be close to $50 \%$ and the disordered components were left to refine with free variables. Soft restraints were used to handle the disorder groups (SIMU, SADI, ISOR, DFIX etc.). The crystals of 1 consists of non-merohedrally twinned domains (49:51 domain ration) and subsequently, a non-merohedral refinement of the crystal data was employed (see details in the CIF file).

Magnetic Measurements: Magnetic susceptibility measurements for 1 were obtained using a Quantum Design SQUID magnetometer MPMS-XL7 operating between 1.8 and 300 K . Direct current (dc) measurements were performed on crushed polycrystalline sample ( 8 mg ), which was restrained with silicon grease, to avoid possible magnetic-field induced torquing, and sealed in a polyethylene membrane under an inert atmosphere for which diamagnetic corrections were applied. The sample was subjected to dc fields of 70 to -70 kOe while alternating current (ac) measurements took place both in the absence and presence of a static dc field ( $H_{\mathrm{dc}}=1200 \mathrm{Oe}$ ).

Magnetic Circular Dichroism (MCD): MCD measurements were recorded on a Jasco J-1700 CD spectrometer and an Oxford SpectromagPT cryogen-free magneto-optical superconducting magnet system. MCD spectra were recorded on mulls prepared in an inert atmosphere of the solid compound of 1 in Parabar 10312 oil from Hampton Research, sandwiched between quartz slides. The spectrum without any applied field was used as the background for the measurements.

## 2. Single-crystal X-ray data, molecular features and structural analysis

Table S1. Crystallographic data and refinement details for complex 1.

| Compound reference | 1 |
| :---: | :---: |

## Structural analysis of 1:

The centrosymmetric molecular structure of 1 (Fig. 1B and S2) consists of four $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{~Tb}^{[1 /]^{+}}\right.$moieties bridged by four $\mu$-tz* ligands forming a diamond-like core, where all four Tbl' metal ions lie on the same plane (Fig. 1B). The average $\mathrm{Tb}^{\prime \prime} \mathrm{Cp}^{*}$ cent bond distance is 2.401(4) $\AA$, which is similar to the respective distance observed in the tz"-bridged $\left[\left(\mathrm{Cp}^{*}{ }_{2} \mathrm{~Tb}_{2}\right)_{2}\left(\mathrm{tz}^{*}\right)(\mathrm{THF})\right] \mathrm{BPh}{ }_{4}$ ( $\mathrm{THF}=$ tetrahydrofuran) " $\mathrm{Tb}_{2}$ " complex (2.405(5) $\AA$ ), while the respective $C p^{*}$ cent-Tb-Cp* cent angle is found to be slightly increased (1: 137.85(4)"; "Tb2" dimer; $\left.136.4(2)^{\circ}\right) .{ }^{[6]}$ The Tb-N bond distances (av. 2.582(2) $\AA$ for Tb 1 and av. $2.603(2) \AA$ for Tb 2 ) are similar to those observed for the "Ln4" (average bond distance: $D_{y-N_{t z}:} 2.585(2) \AA$; Gd- $N_{t z}: 2.618(2) \AA$ ), as expected, although slightly longer than the respective distance on the " $\mathrm{Tb}_{2}$ "; $2.469(2) \AA$. The radical nature of the tetrazine ring is corroborated by the clear elongation of $\mathrm{N} \cdots \mathrm{N}$ bond distances (1.345(3) $\AA$ and $1.331(3) \AA$ ) compared to the neutral free ligand (1.327(6) $\AA) .{ }^{[7]}$ In the "Tb"" core, the shortest intramolecular Tb..Tb distance is $7.350(7) \AA$, while the longest distance separating the diagonals is found to be 10.727 (7) $\AA$ (Fig. S3). The packing arrangement reveals that the "Tb4" units are in relatively close proximity (Fig. S4), where the intermolecular Tb $\cdots$ Tb distances vary between 10.340(10) $\AA$ and 10.754(12) $\AA$ (Fig. S5). These values are in the same range as the largest intramolecular Tb $\cdots \mathrm{Tb}$ distance of 10.727(7) $\AA$.

Fig. S2: ORTEP diagram of 1. Displacement ellipsoids are drawn at the $50 \%$ probability level. Symmetry codes: (a) $x, 1-y, 1-z$; (b) $1-x, 1$ $-y, 1-z ;$ (c) $1-x, y, z$. The benzene solvent molecules have been omitted for clarity.

Fig. S3: Molecular structure of 1 highlighting the intramolecular Tb...Tb distances and angles of the diamond-like core. $\mathrm{Cp}^{*}$, H -atoms, disorder conformers and lattice solvent molecules have been omitted for clarity.

Fig. S4: Molecular packing of 1. Lattice solvent molecules, H -atoms and disorder conformers have been omitted for clarity. Colour code: Tb (purple), C (grey), and N (blue).

Fig. S5: Intermolecular $\mathrm{Tb} \ldots \mathrm{Tb}$ distances. For clarity reasons, partial transparency has been employed and $\mathrm{Cp}^{*}$ as well as H -atoms and lattice solvent molecules have been omitted. Each $\mathrm{Tb} \cdots \mathrm{Tb}$ distance is colour coded.

## 3. Additional magnetic data

## Dc Magnetism Plots:

Fig. S6: Variable temperature $X^{T}$ vs. $T$ plot of 1 under an applied static dc field of 1000 Oe.

Fig. S7: Zero-field-cooled and field-cooled (ZFC/FC) curves for 1 under an applied static field of 1000 Oe. Data were collected at an average sweep rate of $0.3 \mathrm{~K} \mathrm{~min}^{-1}$. ZFC and FC susceptibilities bifurcate at 5.4 K , as indicated by the respective black arrows.

A

B

Fig. S8: Field-dependence plots of the magnetization and the reduced magnetization for 1 collected between 0 and 70 kOe at the respective temperature ranges with an average sweep rate of $15 \mathrm{Oe} / \mathrm{s}$.

Fig. S9: (A) Magnetic hysteresis data for 1 in the respective temperature region collected with an average sweep rate of $25 \mathrm{Oe} / \mathrm{s}$. (B) Zoomedin area of the hysteresis loop at the indicated temperature region.

## Ac Magnetism Plots:

Fig. S10: Frequency-dependence of $X^{\prime}(\mathrm{A})$ and $X^{\prime \prime}(\mathrm{B})$ as a function of temperature in the 9 to 1.8 K temperature range, in the absence of an applied field ( $H_{\mathrm{dc}}=0 \mathrm{Oe}$ ) for $\mathbf{1}$. Solid lines represent best fits to the generalized Debye model.

Table S4. Fitting parameters obtained from CCFit-2 ${ }^{[8]}$ using a generalized Debye model for the ac data of 1 in the absence of a static dc field $\left(H_{d c}=0 \mathrm{Oe}\right)$ in the temperature region of 1.8 to 9 K (Fig. 2A, S10).

## Fit of the temperature- and field-dependent relaxation times for 1:

To further investigate the relaxation dynamics in 1, the extracted relaxation times from the temperature-dependent ac susceptibility ( $X^{\prime}$ and $\chi^{\prime \prime}$ ) when $H_{d c}=0 \mathrm{Oe}$, can be fit to the following equation (S1):

$$
T^{-1}=\tau_{Q T M}{ }^{-1}+T_{0}^{-1} \exp \left(-U_{\text {eff }} / k_{B} T\right)(S 1) .
$$

where a combination of QTM and Orbach processes provided the following best-fit parameters: $\tau_{\text {QTM }}=0.41 \mathrm{~s}, \tau_{0}=1.67 \times 10^{-10} \mathrm{~s}$ and $U_{\text {eff }}=87.8 \mathrm{~cm}^{-1}$. For the field-dependent relaxation times, an excellent fit of the $\tau$ was achieved by using equation (S2):

$$
\tau^{-1}=\left(B_{1} / 1+B_{2} \mathrm{H}_{2}\right)+T_{0}{ }^{-1} \exp \left(-\mathrm{U}_{\mathrm{eff}} / k_{\mathrm{B}} \mathrm{~T}\right)(\mathrm{S} 2)
$$

yielding the following best-fit parameters: $B_{1}=0.25 \mathrm{~s}, B_{2}=1.94 \times 10^{-5} \mathrm{Oe}^{-2}, T_{0}=1.84 \times 10^{-10} \mathrm{~s}$ and $U_{\text {eff }}=88.0 \mathrm{~cm}^{-1}$. Lastly, the extracted relaxation times from the temperature-dependent ac susceptibility ( $x^{\prime}$ and $x^{\prime \prime}$ ) when $H_{d c}=1200 \mathrm{Oe}$, can be fit to the following equation (S3):

$$
\begin{equation*}
T^{1}=T_{0}{ }^{-1} \exp \left(-U_{\text {eff }} / k_{B} T\right) \tag{S3}
\end{equation*}
$$

with the following best-fit parameters: $T_{0}=1.27 \times 10^{-10} \mathrm{~s}$ and $U_{\text {eff }}=89.4 \mathrm{~cm}^{-1}$.

Fig. S12: Field-dependence of the relaxation times $\left(\tau^{1}\right)$ for 1 at a fixed temperature of 6 K with the respective estimated standard deviations (gray bars). The estimated standard deviations of the т were estimated from the $\alpha$-parameters of the generalized Debye fits and the log-normal distribution as described in ref. 8. The relaxation times were obtained from the generalized Debye model (see, Table S4). The optimal static field for which the relaxation times are longest and quantum tunneling of the magnetization is suppressed, is highlighted with a light-pink line. This is the field at which temperature-dependent relaxation studies under a static dc field were completed at (vide infra). The solid red lines represent the best-fit based on eqn. (S2), while the dashed orange and blue lines in represent the individual components of the magnetic relaxation for QTM and Orbach process, respectively.

Fig. S13: Frequency-dependence of $x^{\prime}(\mathrm{A})$ and $x^{\prime \prime}(\mathrm{B})$ as a function of temperature in the 9 to 5.8 K temperature range, under an applied static field of 1200 Oe for 1 . Solid lines represent best fits to the generalized Debye model.

Table S6. Fitting parameters obtained from CCFit-2 ${ }^{[8]}$ using a generalized Debye model for the ac data of 1 in the presence of a static dc field $\left(H_{\mathrm{dc}}=1200 \mathrm{Oe}\right.$ ) in the temperature region of 5.8 to 9 K (Fig. 5C, S13).

Fig. S14: Arrhenius plot of the natural log of the relaxation time, $\tau$, of the magnetization for 1 (teal diamonds) versus the inverse temperature. The red line represents the linear fit to the Arrhenius equation that affords a $U_{\text {eff }}=91.2 \mathrm{~cm}^{-1}$.

## 4. Computational details

Complex 1 consists of four Tb"II ions, two of which are crystallographically independent. These will be labeled according to their crystal structure labels Tb1 and Tb2. The geometry of 1 was extracted from the crystal structure and non-coordinated solvent molecules were removed from the structure. The positions of hydrogen atoms were optimized using density functional theory while the positions of heavier atoms were kept frozen to their crystal-structure coordinates. The geometry optimization was carried out using the Gaussian16 software revision $\mathrm{C} .02{ }^{[9]}$ and the pure GGA exchange-correlation (XC) functional PBE. ${ }^{[10]}$ The $\mathrm{Tb}^{111}$ ions were treated using the $4 f$-incore Stuttgart pseudopotential MWB54 along with a corresponding valence basis set. ${ }^{[11]}$ The remaining atoms were treated using polarized double- $\zeta$ quality def2-SVP basis sets. ${ }^{[12]}$

The local properties of each Tb"II ion were calculated using the crystal-field averaging procedure described in our earlier work. ${ }^{[13]}$ In this approach, only a single $\mathrm{Tb}^{\prime \prime \prime}$ ion was considered in a given calculation. The remaining three $\mathrm{Tb}^{\prime \prime \prime}$ ions in the structure were replaced by diamagnetic $Y^{\text {III }}$ ions. The paramagnetic radical ligands were introduced into the crystal-field in an average manner: first a calculation was carried out where the unpaired electron was removed from the ligands, then another calculation was carried out where an extra electron was added on the radical ligands. In both cases, the radical ligands are diamagnetic. The ab initio crystal-field parameters ${ }^{[14]}$ were extracted from both calculations, and the crystal-field of the radical system was calculated as the arithmetic average of the two crystal fields. The crystal-field operator is then diagonalized to yield the final eigenstates and eigenvalues. This introduces an approximation that is justified when the effect of the unpaired electron on the $\mathrm{Tb}^{111}$ ions is weak and primarily of electrostatic nature. Since lanthanides rarely display strong exchange interaction, this approximation should be well justified. The ab initio crystal-field parameters along with the average parameters are listed in Tables S7 and S8.

A total of four different systems needs to be calculated: the two systems with one electron removed and one electron added for both Tb1 and Tb2. In each case state-averaged complete active space self-consistent field (SA-CASSCF) type multireference calculations were carried out. ${ }^{[15]}$ The calculations were conducted using the Orca code version 5.0.4. ${ }^{[16]}$ The active space consisted of the seven $4 f$ orbitals and eight $4 f$-electrons. All seven septet and 140 pentet states were solved in a single SA-CASSCF calculation for each of the four systems. Electron correlation effects outside the active space were estimated using the second-order $N$-electron valence state perturbation theory (NEVPT2) in its strongly contracted formulation. ${ }^{[17]}$ To reduce the computational costs, a single set of orbitals were used for all states in the NEVPT2 procedure.

Scalar relativistic effects were treated in the multireference calculations using the standard second-order Douglas-Kroll-Heß (DKH) transformation. ${ }^{[18]}$ Spin-orbit coupling (SOC) was introduced using the well-established quasi-degenerate perturbation theory (QDPT) approach, ${ }^{[19]}$ where the spin-orbit coupled Hamiltonian is constructed in a basis of the SA-CASSCF eigenstates and diagonalized to yield the final spin-orbit coupled eigenstates and eigenvalues. The SOC operator was constructed using the spin-orbit mean-field (SOMF) approximation. ${ }^{[20]}$ Polarized triple- $\zeta$ quality SARC-DKH-TZVP basis sets ${ }^{[21,22]}$ were used for the Tb ${ }^{111}$ and $Y^{111}$ ions, and double- $\zeta$ quality $D K H-d e f 2-S V(P)$ basis sets ${ }^{[12,22]}$ with valence-polarization functions for non-hydrogen atoms were used for the remaining atoms. The auxiliary basis sets used in the integral transformation were generated using the "AutoAux" feature in Orca. ${ }^{[23]}$ The $g$ tensors of the quasidoublets were calculated following the well-established methodology. ${ }^{[24]}$ The construction of the crystal-field operators and the calculation of the $g$ tensors was carried out using our own code. In the calculation, the magnetic moments were calculated using the full crystal-field eigenstates and the $L S$ coupling approximation for the construction of the magnetic moment operators.

Similarly to the "Dy4", the principal magnetic axes of all ions in 1 are almost collinear (Fig. S15). The axes are perpendicular to the molecular plane, clearly showing that the strong axiality of the CF arising from the $\mathrm{Cp}^{*}$ ligands is stronger than the equatorial contribution to the CF arising from the bridging tz*- ligands.

Fig. S15: Orientation of the ab initio calculated principal magnetic axes (teal vectors) for 1.

Table S7. Ab initio crystal-field parameters following the Iwahara-Chibotaru ${ }^{[25]}$ notation (in units $\mathrm{cm}^{-1}$ ) calculated for Tb1 ions.

## 5. Magnetic Circular Dichroism (MCD) spectra

Fig. S16: (A) MCD spectra obtained at 1.9 K at different applied magnetic fields in wavenumber scale. (B) Deconvolution of the MCD spectrum obtained at 1.9 K with an applied field of 1 T . The broad band was deconvoluted in four different components related to the ligand absorptions. Black vertical lines in (A) and (B) indicate the position of Tb"I excited states, according to Carnall ${ }^{[26]}$ (Table S11) and agrees with the sharp peaks and dips overlapping the ligand broad bands.

Table S11. Tb ${ }^{\text {"II }}$ excited energy levels according to Carnall. ${ }^{[26]}$

| Energy $/ \mathbf{c m}^{-1}$ | ${ }^{2 S+1 \mathrm{~L}_{J}}$ label |
