#### **Caution!**

Although no accidents were observed during the synthesis, handling, and characterization, all the compounds reported in this work are potentially explosive materials and may explode unpredictably under certain conditions. All the compounds must be synthesized only on a small scale (< 100 mg). Any mechanical actions involving grinding or scratching must be avoided. In addition, all the manipulations must be strictly carried out in a fume hood behind a polycarbonate safety shield. Eye

protection, a face shield, and leather gloves must be worn while handling these compounds.

## 1. General Methods

All reagents were purchased from Aldrich, TCI or GLR Innovations in analytical grade and were used as supplied, if not stated otherwise.  $^1\text{H}$ ,  $^{13}\text{C}\{^1\text{H}\}$  NMR and  $^{15}\text{N}$  spectra were recorded using a 500 MHz (JEOL ECZ500R/S1) NMR spectrometer operating at 500, 125 and 50.69 MHz, respectively. As external standards, chemical shifts in the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra are reported relative to  $\text{Me}_4\text{Si}$  and  $^{15}\text{N}$  NMR to ammonia. The melting point and decomposition temperatures were obtained on a differential scanning calorimeter (S11 6300 EXSTAR) at a scan rate of  $5\text{ }^\circ\text{C min}^{-1}$ . IR spectra were recorded using KBr pellets for solids on a PerkinElmer FT-IR spectrometer. Densities were measured at room temperature by employing BELPycno L Ver1.15 gas pycnometer. High resolution mass spectra quadrupole time-of-flight (HRMS-QTOF) was obtained in ESI mode. Elemental analyses were carried out on an elemental model Vario-EI-III. The impact and friction sensitivity measurements were made using a standard BAM fall hammer (OZM) and a BAM Friction tester (FST ProEX).

Suitable crystals of **2** and **7** were obtained by slow evaporation of their saturated solutions in water. The single-crystal diffraction studies were carried out on a Bruker SMART APEX CCD diffractometer with a Mo  $\text{K}\alpha$  ( $\lambda = 0.710\text{ }^\circ\text{Å}$ ) sealed tube. All crystal structures were solved by direct methods. The program SAINT (version 6.22) was used for the integration of the intensity of reflections and scaling. The program SADABS was used for absorption correction. The crystal structures were solved and refined using the SHELXTL (version 6.12) package.<sup>1</sup> All hydrogen atoms were included in idealized positions, and a riding model was used. Non-hydrogen atoms were refined with anisotropic displacement parameters.

## 2. Experimental Section

### 1,1'-methylenebis(3,5-dinitro-1H-pyrazol-4-ol) (**2**).

A suspension of disodium 3,5-dinitro-4-oxidopyrazol-1-ide (3.00 g, 14.85 mmol) was prepared in 15 mL DMF. To this solution, tetraethylammonium bromide (TEAB, 0.31 g, 1.49 mmol) and diiodomethane (9.94 g, 37.13 mmol) were added. The reaction mixture was heated to  $70\text{ }^\circ\text{C}$  and stirred for overnight. After being cooled, 30 mL cold water was added to the reaction mixture. A small amount of sodium thiosulfate solution was added to absorb the precipitate iodine, and the resultant mixture was stirred for 30 minutes. Without isolating the disodium salt **1**, acidification of the reaction mixture

with 2M H<sub>2</sub>SO<sub>4</sub> to pH~1 was carried out. The obtained precipitate was filtered, and the filtrate was extracted with ethyl acetate (3 x 100 mL), and washed with saturated brine. The combined organic layers were dried over anhydrous MgSO<sub>4</sub> and concentrated under reduced pressure to produce compound **2** as mustard colored solid. Yield: 1.73 g, 64%. #### 4. Theoretical Study

The heats of formation for energetic compounds **2-7** were obtained by using isodesmic reactions. The geometric optimization and frequency analyses of the structures were performed by using B3PW91/6-31G(d,p) level without any symmetry restriction as implemented in Gaussian 09 program.<sup>2,3</sup> All the optimized derivatives are confirmed to be true local energy minima on the potential energy surface without any imaginary frequencies. All calculated gas-phase enthalpies for covalent materials are converted to solid-phase values by subtracting the empirical heat of sublimation obtained based on the molecular surface properties.<sup>4</sup> For salts **3-7**, the solid phase heats of formation were calculated based on the Born–Haber energy cycle.<sup>5,6</sup>

## 10. $^{15}\text{N}$ NMR Analysis

Fig.S34:  $^{15}\text{N}$  NMR spectra of compounds **2**, **3**, and **6**

The  $^{15}\text{N}$  NMR spectral analysis for compounds **2**, **3**, and **6** was done by taking nitromethane as a reference (Fig. S34). The peaks of the nitrogens of the nitro groups fall in the range of -25.6 ppm to -34.8 ppm. After formation of anion in salts **3** and **6**, an upfield shift is observed in N1 (from -199.6 ppm in **2** to -202.5 in **3** and -205.5 ppm in **6**, whereas N2 observed a downfield shift (from -84.1 ppm in **2** to -74.0 in **3** and -75.0 ppm in **6**). Peak of the ammonium cation in **3** was found to be at -362.3 ppm, and amino groups in the cation of **6** showed peaks in the range of -333.0 and -327.5 ppm.
