### 1.1 Experimental Methods

## General Information

The manipulations described herein were performed under an inert argon atmosphere with rigorous exclusion of air and water using Schlenk line and glovebox techniques. $N$-Hexane was dried over calcium hydride. Diethyl ether and THF were dried over a $\mathrm{Na} / \mathrm{K}$ alloy. Toluene was distilled over potassium. Potassium bis(trimethylsilylamide) $\left(\mathrm{KN}\left[\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{3}\right]_{2}\right)$ was purchased from Sigma-Aldrich, dissolved in toluene, centrifuged, filtered, and recrystallised at $-35{ }^{\circ} \mathrm{C}$. Triphenylbismuth $\left(\mathrm{BiPh}_{3}\right)$ was purchased from Sigma-Aldrich and recrystallised from hexane at $-35{ }^{\circ} \mathrm{C} .1,2,3,4,5-$ Pentamethylcyclopentadiene ( $\mathrm{HCp}^{*}$ ) was purchased from Sigma-Aldrich and dried over $4 \AA$ sieves. Anhydrous yttrium chloride $\left(\mathrm{YCl}_{3}\right)$ and allylmagnesium chloride ( 2.0 M in THF) were purchased from Sigma-Aldrich and used as received. KCp* was synthesised by deprotonation of $\mathrm{HCp}{ }^{*}$ with $\mathrm{K}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right] .{ }^{1} \mathrm{KC}_{8},{ }^{2}\left(\mathrm{HNEt}_{3}\right)\left(\mathrm{BPh}_{4}\right)$, ${ }^{3}$ and $\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}\left(\mathrm{BPh}_{4}\right),{ }^{4}$ were prepared according to literature procedures. A PerkinElmer 2400 Series II CHNS/O analyser was used for CHN elemental analyses.
$\left[\mathrm{K}(\mathrm{THF})_{4}\right]_{2}\left[\mathrm{Cp}_{2}{ }_{2} \mathbf{Y}_{2} \mathrm{Bi}_{6}\right]$ (1). In an argon filled glovebox, $\mathrm{BiPh}_{3}(19.9 \mathrm{mg}, 0.0451 \mathrm{mmol})$ was dissolved in 2 mL of THF and added to a 5 mL colorless solution of $\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}\left(\mathrm{BPh}_{4}\right)(102.0 \mathrm{mg}$, $0.1503 \mathrm{mmol})$ in THF. Subsequently, $\mathrm{KC}_{8}(22.6 \mathrm{mg}, 0.165 \mathrm{mmol})$ was added at once to the reaction mixture and stirred for 15 minutes at room temperature. The dark red solution was filtered to remove the black and colorless insoluble material, presumably graphite and $\mathrm{KBPh}_{4}$. The solvent was removed in vacuo to afford a dark solid which was washed three times with 5 mL of hexane and twice with 5 mL of toluene to remove the byproduct $\mathrm{Cp}^{*}{ }_{2} \mathrm{YPh}$ (THF) (2). The remaining black solid was dissolved in 5 mL of THF and filtered to obtain a dark brown solution, which was evaporated to dryness. The solids were dissolved in 1 mL of THF. Black, block-shaped crystals, suitable for single crystal X-ray diffraction analysis were crystallised from the THF solution via vapor diffusion of hexane at $-35{ }^{\circ} \mathrm{C}$ in $12 \%$ yield, based on $\mathrm{BiPh}_{3}$. Anal. Calc. for $\mathrm{Y}_{2} \mathrm{Bi}_{6} \mathrm{C}_{20} \mathrm{H}_{30} \mathrm{~K}_{2} \cdot 0.5 \mathrm{THF}: \mathrm{C}, 14.55 ; \mathrm{H}, 1.89 ; \mathrm{N}, 0.0$. Found. C, $14.53 ; \mathrm{H}, 1.42 ; \mathrm{N}, 0.36$. Anal Calc. for $\mathrm{YC}_{30} \mathrm{H}_{43} \mathrm{O}: \mathrm{C}, 70.85 ; \mathrm{H}, 8.52 ; \mathrm{N}, 0.0$. Found. C, $70.24 ; \mathrm{H}, 9.10 ; \mathrm{N}, 0.14$.

## X-ray Crystallography.

A black block-shaped crystal of $1,0.20 \times 0.149 \times 0.077 \mathrm{~mm}^{3}$, was mounted on a nylon loop with Paratone oil. Data were collected using a XtaLAB Synergy, Dualflex, HyPix diffractometer equipped with an Oxford Cryosystems low-temperature device, operating at $\mathrm{T}=100.0(1) \mathrm{K}$.

Data were measured using $\omega$ scans using Mo Ka radiation (microfocus sealed X-ray tube, 50 kV , 1 mA ). The total number of runs and images was based on the strategy calculation from the program CrysAlisPro (Rigaku, V1.171.41.90a, 2020). Cell parameters were retrieved using CrysAlisPro (Rigaku, V1.171.41.90a, 2020) software and refined using CrysAlisPro (Rigaku, V1.171.41.90a, 2020). Data reduction was performed using the CrysAlisPro (Rigaku, V1.171.41.90a, 2020) software, which corrects for Lorentz-polarisation. A numerical absorption correction based on Gaussian integration over a multifaceted crystal model empirical absorption
correction using spherical harmonics was implemented in the SCALE3 ABSPACK scaling algorithm.

The structure was solved in the space group $P 2_{1} / n$ by using dual methods with the ShelXT (Sheldrick, 2015) structure solution program. ${ }^{5}$ The structure was refined by least squares using version 20189/2 of $\mathrm{XL}^{6}$ incorporated in Olex2. ${ }^{7}$ All non-hydrogen atoms were refined anisotropically. Hydrogen atom positions were calculated geometrically and refined using the riding model.

A colorless block-shaped crystal of 2, $0.48 \times 0.4 \times 0.17 \mathrm{~mm}^{3}$, was mounted on a nylon loop with Paratone oil. Data were collected using a XtaLAB Synergy, Dualflex, HyPix diffractometer equipped with an Oxford Cryosystems low-temperature device, operating at $T=100.0(1) \mathrm{K}$.

Data were measured using $\omega$ scans using Mo Ka radiation (microfocus sealed X-ray tube, 50 kV , 1 mA ). The total number of runs and images was based on the strategy calculation from the program CrysAlisPro (Rigaku, V1.171.41.90a, 2020). Cell parameters were retrieved using CrysAlisPro (Rigaku, V1.171.41.90a, 2020) software and refined using CrysAlisPro (Rigaku, V1.171.41.90a, 2020). Data reduction was performed using the CrysAlisPro (Rigaku, V1.171.41.90a, 2020) software, which corrects for Lorentz-polarisation. A numerical absorption correction based on Gaussian integration over a multifaceted crystal model empirical absorption correction using spherical harmonics was implemented in the SCALE3 ABSPACK scaling algorithm.

The structure was solved in the space group $P 2_{1} / c$ by using dual methods with the ShelXT (Sheldrick, 2015) structure solution program. ${ }^{5}$ The structure was refined by least squares using version 20189/2 of XL $^{6}$ incorporated in Olex2. ${ }^{7}$ All non-hydrogen atoms were refined anisotropically. Hydrogen atom positions were calculated geometrically and refined using the riding model.

## UV-Vis Spectroscopy.

UV-vis spectra were collected with an Agilent Cary 60 spectrophotometer at ambient temperature from 200 to 1100 nm . Samples were prepared in an argon-filled glovebox and measured in a 1 cm quartz cuvette. The spectrum is baseline corrected from a sample of dry and filtered THF.

## Computational Methods

Density functional theory (DFT) calculations were carried out using the program Gaussian V16 (Rev. B01) ${ }^{8}$ on the coordinates of the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion as obtained from single-crystal X-ray analysis in singlet state. The geometry was successively optimised with a three step strategy: 1) $321 \mathrm{G}(\mathrm{C}, \mathrm{H}, \mathrm{Y}) /$ def2-SVP(Bi); ${ }^{9,10} \quad$ 2) $631+\mathrm{G}^{*}(\mathrm{C}, \mathrm{H}) / \mathrm{SVPD}(\mathrm{Y}, \mathrm{Bi}) ;{ }^{; 11-15}$
$631+\mathrm{G}^{*}(\mathrm{C}, \mathrm{H}) / E C P 60 M D F \_V D Z(\mathrm{Bi}) / E C P 28 M D F \_V D Z(Y) .{ }^{11-14,16,17}$ The optimisations were carried out with the functionals TPSSTPSS, ${ }^{18}$ TPSSh, ${ }^{18,19}$ B3LYP, ${ }^{20-23}$ CAM-B3LYP, ${ }^{24}$ BP86, ${ }^{25,26}$ $\omega 97 x D,{ }^{27}$ PBEPBE,,${ }^{28,29}$ and PBEO ${ }^{28-30}$ with the fully relativistic pseudopotentials ECP28MDF and ECP60MDF on the $\mathrm{Y}^{17}$ and $\mathrm{Bi}^{31}$ atoms, respectively, and under consideration of the empirical dispersion correction GD3 by Grimme. ${ }^{32,33}$ After all optimisations converged on level 3) of theory
and were confirmed to be minimum structures via frequency calculations (one imaginary frequency at $\sim 10 \mathrm{~cm}^{-1}$, associated with an in-plane rotation of the $\mathrm{Cp}^{*}$ rings was returned in all cases and could not be eliminated through additional optimisations) the metrical parameters of the obtained structures were compared with the coordinates obtained from single-crystal X-ray diffraction analysis in order to find the exchange correlation functional best-suited to describe the bonding situation in the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion. Here, the PBE0 functional proved to be best-suited, as deduced by the mean deviation (MD), mean square error (MSE), root mean square error (RMSE) and mean absolute percentage error (MAPE), Figure S5. As a general note, all DFT functionals predict longer $\mathrm{Bi}-\mathrm{Bi}$ and $\mathrm{Y}-\mathrm{Bi}$ bonds, thereby underestimating the covalent character and/or aromatic stabilization of these bonds to some extent. Subsequently, the negative charge of the cluster was compensated by employing the polarisable conductor calculation model (CPCM, with parameters chosen for tetrahydrofuran) ${ }^{34,35}$ in an additional optimisation step on the PBE0/6311+G*(C,H)/ECP_AVTZ(Bi,Y) level of theory. Single point calculations were carried out on the obtained structure for natural localised molecular orbital (NLMO) ${ }^{36}$ with NBO6, ${ }^{36}$ nucleus independent chemical shift (NICS), ${ }^{32}$ quantum theory of atoms in molecules (QTAIM) ${ }^{37,38}$ and electron localisation function (ELF) calculations. The latter two analyses were conducted using the program MultiWfn. ${ }^{39}$ TDDFT calculations were carried out on the CPCM-optimised structure for 75 excited states for the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion on the $6311+\mathrm{G}^{*}(\mathrm{C}, \mathrm{H}) / E C P \_A V T Z(\mathrm{Bi}, \mathrm{Y})$ level using the PBE0 functional with dispersion correction GD3 and implicit solvent model CPCM for THF. UV-vis spectra were simulated via application of a 0.1 eV Gaussian broadening using the MultiWfn program. The transitions were empirically shifted by 0.4 eV .

$\rho(\mathrm{r})$ : Density of all electrons; $G(r)$ : Lagrangian kinetic energy; $K(r)$ : Hamiltonian kinetic energy; $V(\mathrm{r})$ : Potential energy;
$H(r)$ : Energy density; $\nabla^{2}$ : Laplacian of electron density; $\varepsilon$ : Ellipticity of electron density; MBO: Mayer Bond Order; $\lambda_{\pi 3}$ : Curvature of the electron density perpendicular to RCP; SA: Shannon aromaticity index.

Figure S7. Plot of the electron localisation function (ELF) of the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion along the plane spanned by the $\mathrm{Y}^{4}, \mathrm{Bi}^{6}, \mathrm{Bi}^{7}$ and $\mathrm{Bi}^{8}$ atoms. Values close to 1 refer to ideal localisation while values below 0.5 indicate strong delocalisation. Alternating local maxima and minima around the heavy atoms can be attributed to the electronic (shell) structure of these atoms, which is reliably reproduced through the ELF. ${ }^{42}$ Most prominently, the local maxima on the Bi atoms facing outside the cluster core represent their lone electron pairs. Data of the $\mathrm{C}-\mathrm{H}$ interaction occurring in this plane were omitted for clarity.

Figure S8. Top: Plot of the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion with printed ghost atoms used for the calculation of the nuclear-independent chemical shift (NICS). Small green spheres, large pink and purple spheres represent ghost, Y and Bi atoms, respectively. Bottom: Distance-dependent plots of the calculated NICS values. Pink dotted lines represent positions of equatorial Bi atoms (left), green and purple dotted lines represent positions of Y atoms and $\mathrm{Cp}^{*}$ centroids (right), respectively. The more negative the NICS values, the stronger the deshielding of the respective ghost atoms.

Figure S9. Distance-dependent plots of the calculated NICS values for the $\mathrm{Bi}_{6}{ }^{6-}$ core without capping ( $\left.C p^{*} Y\right)^{2+}$ units. Green and purple dotted lines represent positions of $Y$ atoms and $C p^{*}$ centroids. The more negative the NICS values, the stronger the deshielding of the respective ghost atoms.

### 1.4 UV-Vis spectroscopy and TDDFT calculations

Figure S10. UV-Vis absorption spectra of 1 recorded at $100 \mu \mathrm{~mol} / \mathrm{L}, 50 \mu \mathrm{~mol} / \mathrm{L}$ and $20 \mu \mathrm{~mol} / \mathrm{L}$ concentrations in THF at room temperature (left). Comparison of the experimental UV-Vis spectrum of 1 ( $100 \mu \mathrm{~mol} / \mathrm{L}$ ) with Gaussian-broadened calculated spectrum (dashed red) and calculated transitions (black bars). Extinction coefficients represent y-dimension of experimental and calculated spectra, while the oscillator strength represents the $y$-dimension for the experimental and calculated spectra.

Several strong absorptions are predicted in the visible region that were deconvoluted to identify major transitions involved within these bands. The first calculated absorption is found at 681.2 nm and involves a $\mathrm{HOMO} \rightarrow \mathrm{HOMO}+3$ transition. The HOMO here can be described as a $\mathrm{Bi}_{6}{ }^{6-} \pi-$ type orbital. Towards smaller wavelengths, two sets of double absorptions are predicted at $593.8 / 592.6 \mathrm{~nm}$ and $553.3 / 551.4 \mathrm{~nm}$, which comprise dominant HOMO-1 $\rightarrow \mathrm{HOMO}+3$ transitions for the higher wavelengths, and $\mathrm{HOMO}-2 \rightarrow \mathrm{HOMO}+3$ transitions for the lower wavelengths. The occupied orbitals involved are primarily $\sigma$-bonding $\mathrm{Bi}_{6}{ }^{6-}$ featuring considerable overlap with the yttrium atoms, while the virtual orbital $\mathrm{HOMO}+3$ is composed of $\mathrm{Bi}_{6}{ }^{6-} \sigma^{*}$ orbitals. A third set of double excitations is predicted at $526.2 / 524.6 \mathrm{~nm}$, comprising $\mathrm{HOMO} \rightarrow \mathrm{HOMO}+5$ and $\mathrm{HOMO} \rightarrow$ $\mathrm{HOMO}+6$ transitions, where both virtual orbitals are best described as $\mathrm{Bi}_{6}{ }^{6-} \pi^{*}$ orbitals. At 446.4 nm , a HOMO $\rightarrow \mathrm{HOMO}+7$ transition is calculated, where the virtual orbital exhibits $\pi^{*}$ characteristics encompassing both the $\mathrm{Bi}_{6}{ }^{6-}$ and $\mathrm{Cp}^{*}$ moieties.

Table S7. TDDFT-calculated transitions for the $\left[\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}_{2} \mathrm{Bi}_{6}\right]^{2-}$ anion on the $6311+\mathrm{G}^{*}(\mathrm{C}, \mathrm{H}) / E C P \_A V T Z(\mathrm{Bi}, \mathrm{Y})$ level using the PBEO functional with dispersion correction GD3 and implicit solvent model CPCM for THF. The calculated excitation energies were empirically red shifted by 0.4 eV . HOMO: 156, LUMO: 157. Oscillator strength cutoff value: 0.07. Print threshold for individual transitions: 10\%. Donor/acceptor orbitals are visualized for the dominant transitions with weights $>40 \%$. Isovalue for orbital depictions: 0.015 .
