General Experimental

All the reactions has been carried out in an oven-dried round bottomed flask. Commercial grade solvents were distilled prior to use. Column chromatography has been performed using silica gel (100-200 Mesh) with hexanes and ethyl acetate mixture. Thin layer chromatography (TLC) has been checked on silica gel GF254 plates. The spots on TLC plate have been visualized with UV light (254 nm) and/or staining over I₂ chamber.

Proton and carbon nuclear magnetic resonance spectra (¹H NMR, ¹³C NMR) are recorded on a 400 MHz (¹³C NMR, 101 MHz), 500 MHz (¹³C NMR, 126 MHz) spectrometer (spectra are recorded with a BRUKER-DMX-NMR) and 600 MHz (¹H NMR, 600 MHz; ¹³C NMR, 151 MHz; ¹⁵N NMR, 61 MHz; spectra are recorded with a JEOL JNM-ECZ-600R/M1) spectrometer, having solvent resonance as internal standard (¹H NMR: CDCl₃ at 7.26 ppm, DMSO-d₆ at 2.49 ppm, Acetone-d₆ at 2.04 ppm, CD₃CN at 1.93 ppm; ¹³C NMR: CDCl₃ at 77.0 ppm, DMSO-d₆ at 39.5 ppm, Acetone-d₆ at 29.8 & 206.5 ppm, CD₃CN at 1.3 & 118.3 ppm). Few cases tetramethylsilane (TMS) at 0.00 ppm has been used as reference standard. The chemical shift values (ppm) are expressed relative to the chemical shift of [deuterated] solvent or to the external standard liq. NH₃ without correction (¹⁵N NMR). Data for ¹H NMR are reported as follows: chemical shift (ppm), multiplicity (s = singlet; bs = broad singlet; d=doublet; bd = broad doublet; dd = doublet of doublet; dt = doublet of triplet; tt= triplet of triplet; t = triplet; bt= broad triplet; q = quartet; pent =pentet, m =multiplet), coupling constants *J* in (Hz), and integration. ¹³C NMR is reported in terms of chemical shift (ppm). Melting points and decomposition temperatures are determined by DSC and TG-DSC measurements. IR spectra are recorded on FT/IR spectrometer and are reported in cm⁻¹. High resolution mass spectra (HRMS) are obtained in ESI mode. X-ray data are collected on a 'Bruker D8 VENTURE Photon III detector' and Rigaku Oxford Hypix-3000 diffractometer using Mo-K α radiation (0.71073 Å) and Cu-K α radiation (1.54 Å).

In most cases, the X-Ray crystallography data of the energetic compounds are collected at low temperature. The strong intermolecular interactions in the crystal unit cell affect the X-ray diffraction [see Effect of Strong Intermolecular Interaction in 2D Inorganic Molecular Crystals, Xin Feng, Xingliang Peng, Baixin Peng, Zexin Li, Wentao Huang, Sijie Yang, Ke Pei, Zongdong Sun, Fuqiang Huang, Huiqiao Li, Zhigang Shuai, and Tianyou Zhai, *Journal of the American Chemical Society* **2021**, *143* (48), 20192-20201]. Thus, most of the X-ray crystal data are collected in different temperature; we report the best diffraction results. Whereas X-ray data for compound **8** and **12** are collected at 298K.

The Hirschfeld surfaces analysis of compound **12** was independently examined at low temperature and room temperature as shown in Table 1. We did not see significant variation of atomic interactions (listed in the table) in the crystal packing. We therefore believe that the thermal expansion is not greatly affected with respect to temperature.

Hirshfeld Surface Analysis¹¹

The Hirshfeld surface image shown in Figure4 (in the manuscript body), the red spots signify the high contact populations, while blue and white spots are for low contact populations. This suggests that the negative (red) or positive value (blue and white) of d_{norm} depends on the intermolecular contacts being shorter (red) or longer (blue and white) than the Vander Waals separations. For each point on the Hirshfeld surface, the normalized contact distance (d_{norm}) was determined by the equation shown below.

$$[d_{norm} = (d_i - d_i^{vdW})/r_i^{vdW} + (d_e - d_e^{vdW})/r_e^{vdW}]$$

In which, d_i is measured from the surface to the nearest atom interior to the surface interior, while d_e is measured from the surface to the nearest atom exterior to the surface interior, where r_i^{vdW} and r_e^{vdW} are the Van der Waals radii of the atoms. Hirshfeld surface graphs and two-dimensional fingerprint plots of **8**, **9**, **11**, and **12** were analyzed using Crystalexplorer17.5 software and Hirshfeld surface calculation of **11** as shown in Figure S12 (Hirshfeldplots of **8**, **9**, and **12** are shown in Figure 4, manuscript body).

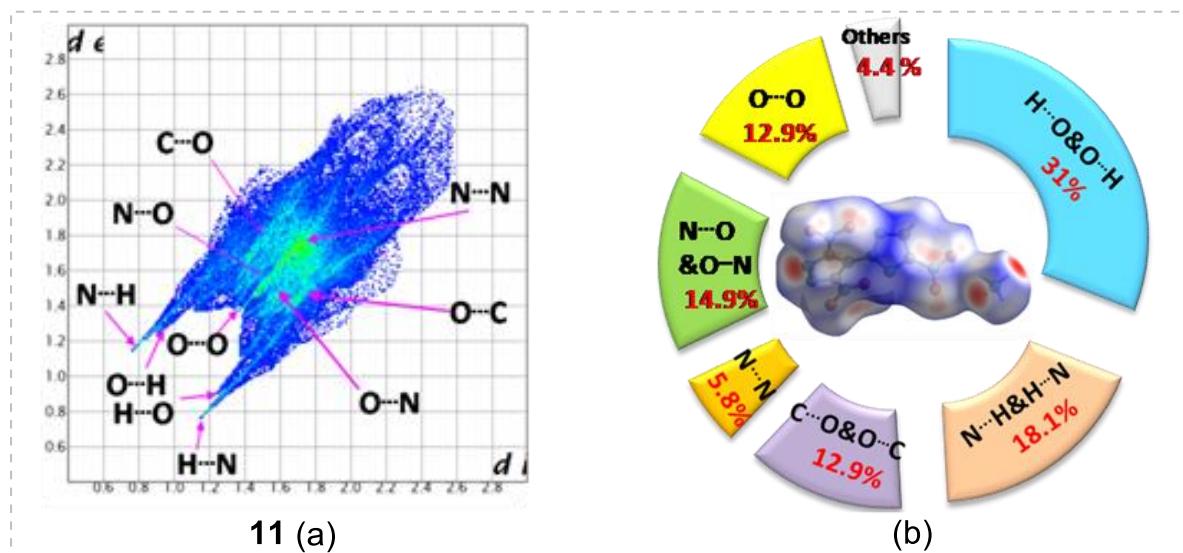

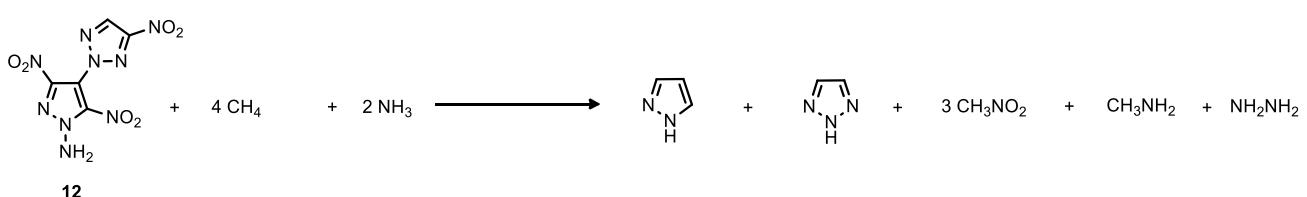

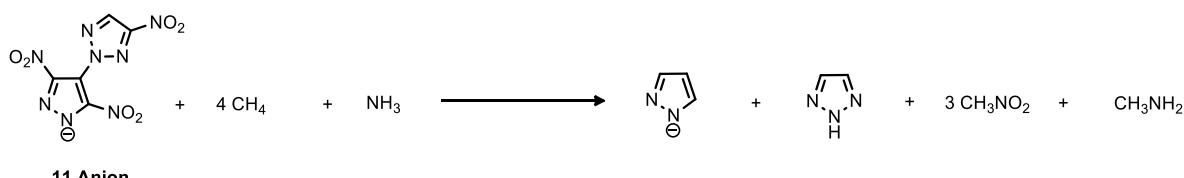

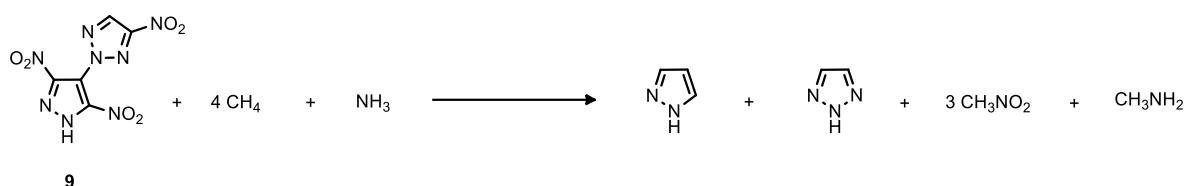

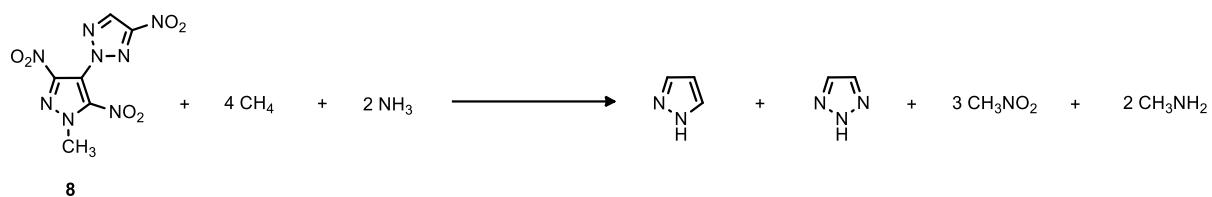

Figure S7: Hirshfeld surface calculation of **11** as well as two-dimensional finger print plot in the crystal structure. Hirshfeld surface graph (centre of pie graph) with proximity of close contacts around **11** molecules (white, $d = \text{Van der Waals (vdW) distance}$; blue, $d > \text{vdW distance}$; red, $d < \text{vdW distance}$). The pie graph (b) for **11** and show percentage contributions of the individual atomic contacts to the Hirshfeld surface.

Hirschfeld surface and the related 2D fingerprint plots mainly reveals the intermolecular interactions [such as hydrogen bonding (HB), and π -stacking] of the energetic crystals; these interactions generally determine the packing structure and further the properties and performances of an energetic compound. In general, the large population of O...H/H...O and N...H/H...N interactions makes the molecule more stable and therefore is less sensitive. Accordingly, compound **8** (N-methyl trinitro-pyrazolo-triazole; IS: 40 J) and **12** (N-amino trinitro-pyrazolo-triazole; IS: 35 J) are relatively less sensitive than trinitro-pyrazolo-triazole (TNPT) (IS: 35 J) due to more O...H/H...O and N...H/H...N interactions in the crystal packing {see: Hirshfeld Surface Method and Its Application in Energetic Crystals, Shijie Li, Rupeng Bu, Rui-jun Gou, and Chaoyang Zhang, *Crystal Growth & Design*, **2021**, 21 (12), 6619-6634].
