**$\Delta$ -Machine Learning for Quantum Chemistry Prediction of  
Solution-phase Molecular Properties at Ground and Excited  
States**

**Text S1.** Procedures to obtain the EC descriptor.

To obtain the energy component descriptors through Terachem, four sets of single-point energy calculations were carried out. (1) The gas phase calculation was first conducted to produce the gas-phase single-point energy (index 1, index as in Table S2). (2) The converged molecular orbitals (MOs) of the gas phase calculations were treated as the initial guess of a new round of PCM calculation. By collecting the energy of the first step of the self-consistent-field (SCF) calculation, which we assumed to be the total energy of a solute under an unrelaxed potential field potential field, the index 2 component can be achieved. With the PCM calculation finished, we can obtain the final energy as the index 4 component and a relaxed potential field. (3) The relaxed potential field combined with the MO initial guess extracted from the gas phase calculation was then treated as the input files in another round of PCM calculation. In this calculation, the index 5 component can be attained by reading the total energy of the first step of the SCF calculation. (4) Similarly, the index 3 component was obtained by incorporating the MO initial guess from the (2) step and reading the energy of the first step of the SCF calculation. The other components can then be obtained by directly extracting from previous output files or be calculated based on the first 5 components.

**Text S2.** Feature engineering by adding SS or EC features to cFP.

Here, we decided not to use RF-RFA to determine features to be added, because the initial RF feature importance ranking may be unfair when the few features of SS or EC are combined with the high-dimensional cFP. Hence, we used the sequential feature selection (SFS)<sup>1</sup> approach on the ROAS dataset to avoid RF rank bias, because SFS does not need an initial rank. With the raw  $E_{\text{abs}}$  and Morgan FP set as the initial feature, components of SS, EC, and five solvent constant descriptors from cFP are added incrementally. In each SFS cycle, each of the  $m$  unselected candidate features will be tentatively combined with the  $n$  previously selected features to retrain a GB model, resulting in  $m$  new models in total. The candidate feature used in the best performing model among the  $m$  models will be officially added to the feature set. This is drastically different from RF-RFA, where each cycle only retrains the one model using the existing features plus the candidate feature with the highest initial RF rank if this one model makes even tiny MAE improvement. The feature addition was stopped at the fourth round (SI Table S23) due to the increase of MAE after adding SA, C-PCM cavity surface, and ET30 as the best among candidates, but we still tested a few rounds of addition manually, observing only small fluctuations occurred near the best performance.

**Table S1.** Hyperparameter tuning search space for each type of ML model. To avoid overtraining ML models, hyperparameter tuning was performed for all models using hyperopt<sup>2</sup>. Adaptive Tree Parzen Estimators (TPE) was used as the searching algorithm with a maximum of 200 trials. Hyperparameters are named as in scikit-learn and searching space as in hyperopt.<sup>2</sup>

| ML model | hyperparameter     | searching space                                                                       |

**Table S2.** The 10 energy components of the energy component descriptor.

| index | Energy Component                                                                                          |
|-------|-----------------------------------------------------------------------------------------------------------|
| 1     | $\langle \Psi^{(0)}   H   \Psi^{(0)} \rangle$                                                             |
| 2     | $\langle \Psi^{(0)}   H + V^{(0)} / 2   \Psi^{(0)} \rangle$                                               |
| 3     | $\langle \Psi^{(1)}   H   \Psi^{(1)} \rangle$                                                             |
| 4     | $\langle \Psi^{(1)}   H + V^{(1)} / 2   \Psi^{(1)} \rangle$                                               |
| 5     | $\langle \Psi^{(0)}   H + V^{(1)} / 2   \Psi^{(0)} \rangle$                                               |
| 6     | $\langle \Psi^{(0)}   H + V^{(1)} / 2   \Psi^{(0)} \rangle - \langle \Psi^{(0)}   H   \Psi^{(0)} \rangle$ |
| 7     | $\langle \Psi^{(1)}   H   \Psi^{(1)} \rangle - \langle \Psi^{(0)}   H   \Psi^{(0)} \rangle$               |
| 8     | $\langle \Psi^{(1)}   H + V^{(1)} / 2   \Psi^{(1)} \rangle - \langle \Psi^{(1)}   T   \Psi^{(1)} \rangle$ |
| 9     | $\langle \Psi^{(1)}   T   \Psi^{(1)} \rangle$                                                             |
| 10    | $\langle \Psi^{(1)}   H   \Psi^{(1)} \rangle - \langle \Psi^{(1)}   T   \Psi^{(1)} \rangle$               |

**Table S3.** The best  $\Delta$ -ML MAE of all combinations of ML models and energy component descriptors predicting on three respective  $\omega$ B97(-D3) functional calculated datasets. The ‘removed’ column means the linear dependent components were removed from the original 10 energy components. The ‘origin’ column means using the 10 energy components as mentioned in Table S2. There is no change of the performance after removing the redundant components.

| dataset | removed     | origin      |
|---------|-------------|-------------|
| OROP    | RF/0.166 V  | RF/0.166 V  |
| OMROP   | ANN/0.516 V | ANN/0.516 V |
| ROAS    | RF/0.458 eV | RF/0.458 eV |

**Table S4-S6.**  $\Delta$ -ML model performance for each descriptor on various datasets without adding the raw QM calculated results as features.

**Table S4.** OROP data set,  $\Delta$ -ML redox potential,  $\omega$ B97-D3 functional.

| 128  | 0.459  | 0.350 | 0.322 | 0.321 | 0.363 |

**Table S22.** A comparison of FP ML performance ( $\omega$ B97/GB) between direct generation of 1024, 512... bits Morgan fingerprints from RDKit, and generating 3072 bits Morgan fingerprints from RDKit and then using “SelectKBest” reducing bits to 1024, 512... on ROAS predicting absorption energy.

| MAE (eV)          | 1024  | 512   | 256   | 128   |
|-------------------|-------|-------|-------|-------|
| directly generate | 0.311 | 0.326 | 0.330 | 0.321 |
| “SelectKBest”     | 0.540 | 0.572 | 0.549 | 0.570 |

**Table S23.** ML performance ( $\omega$ B97/GB) of each step of SFS on ROAS data set predicting absorption energy. The initial features are set as Morgan fingerprints (1024 bits) and the calculated absorption energy. The test set MAEs are lower than the validation set here because the model was trained on the whole training set (80% of all data) before predicting on the test set. In contrast, the MAEs of validation set are the averaged 5-fold validation score by training only 64% of all data. SA, ET are two of the solvent constants. 6 is the index 6 energy component of EC descriptors. C-PCM cavity surface and spin are two features of SS descriptors.

| Feature                                                                    | validation set<br>MAE (eV) | test set<br>MAE (eV) |
|----------------------------------------------------------------------------|----------------------------|----------------------|
| FP + $E_{\text{calculated}}$ + SA                                          | 0.3232                     | 0.299                |
| FP + $E_{\text{calculated}}$ + SA + C-PCM cavity surface                   | 0.3221                     | 0.295                |
| FP + $E_{\text{calculated}}$ + SA + C-PCM cavity surface + ET30            | 0.3208                     | 0.301                |
| FP + $E_{\text{calculated}}$ + SA + C-PCM cavity surface + ET30 + 6        | 0.3222                     | 0.296                |
| FP + $E_{\text{calculated}}$ + SA + C-PCM cavity surface + ET30 + 6 + spin | 0.3221                     | 0.306                |
