## Computational Details

The structure prediction method was based on a global minimization of free energy surfaces combining *ab initio* total-energy calculations methodology, as implemented in the CALYPSO (Crystal structure AnaLYsis by Particle Swarm Optimization) code.<sup>1,2</sup> The structures of  $Ta_xO_y$  ( $x = 1, y = 1-5$ ;  $x = 2, y = 1, 3, 5, 7$ ;  $x = 3, y = 1$ ) were searched with simulation cell sizes of 1-4 formula units (f.u.) at the selected pressures of 1 atm and 50, 100, 200, 300 GPa. In the first step, random structures with certain symmetry were constructed in which atomic coordinates were generated by the crystallographic symmetry operations. Local optimizations using the VASP code<sup>3</sup> were done with the conjugate gradients method and stopped when the total enthalpy changes became smaller than  $1 \times 10^{-5}$  eV per cell. After processing the first-generation structures, 60% of them with lower enthalpies were selected to construct the next generation structures by PSO (Particle Swarm Optimization). 40% of the structures in the new generation were randomly generated. A structure fingerprinting technique of bond characterization matrix was applied to the generated structures, so that identical structures are strictly forbidden. These procedures significantly enhanced the diversity of the structures, which was crucial for structural global search efficiency. In most cases, structural searching simulations for each calculation were stopped after generating 1000 ~ 1200 structures (e.g., about 20 ~ 30 generations).

To further analyze the structures with higher accuracy, we selected a number of structures with lower enthalpies and performed structural optimization using density functional theory within the generalized gradient approximation<sup>4</sup> as implemented in the VASP code. In all the calculations, the cutoff energy for the expansion of wavefunctions in plane waves was set to 750 eV, and the Monkhorst-Pack  $k$ -mesh with a grid spacing of  $2\pi \times 0.025 \text{ \AA}^{-1}$  was selected to meet well energy convergence within  $\sim 1$  meV/atom. The electron-ion interaction was described by the projector-augmented-wave potentials with  $5s^25p^65d^36s^2$  and  $2s^22p^4$  configurations considered as valence electrons for Ta and O atoms, respectively.

In order to further test the reliability of the adopted pseudopotentials for Ta and O, the validity of the projector augmented wave (PAW) pseudopotentials from the VASP library were checked by comparing the calculated Birch-Murnaghan equation of state with those obtained from the full-potential linearized augmented plane-wave method (LAPW, as implemented in WIEN2k).<sup>5</sup> The Birch-Murnaghan equation of states derived from PAW and LAPW methods were almost identical (Fig. S0). Thus, our adopted pseudopotentials were feasible in the range of 0-300 GPa.

The electron-phonon coupling calculations were carried out with the density functional perturbation theory (DFPT) in the QUANTUM ESPRESSO package.<sup>6</sup> We employed the ultrasoft pseudopotentials with  $5s^25p^65d^36s^2$  and  $2s^22p^4$  as valence electrons for Ta, and O atoms, respectively. The kinetic energy cutoff and width of the Gaussians were chosen as 100 and 0.05 Ry. To reliably calculate electron-phonon coupling in metallic systems, we need to sample dense  $k$ -meshes for electronic Brillouin zone integration and enough  $q$ -meshes for evaluating average contributions from the phonon modes. Dependent on the specific structures of stable compounds, different  $k$ -meshes and  $q$ -meshes were used:  $10 \times 10 \times 10$   $k$ -meshes and  $5 \times 5 \times 2$   $q$ -meshes for  $TaO_3$  in the  $Pm-3n$  structure,

$16 \times 16 \times 21$  k-meshes and  $4 \times 4 \times 3$  q-meshes for TaO<sub>2</sub> in the  $I4/mmm$  structure,  $15 \times 15 \times 6$  k-meshes and  $5 \times 5 \times 2$  q-meshes for TaO in the  $P6_3/mmc$  structure,  $6 \times 10 \times 10$  k-meshes and  $2 \times 5 \times 5$  q-meshes for Ta<sub>2</sub>O in the  $P2_1/m$  structure,  $8 \times 8 \times 8$  k-meshes and  $4 \times 4 \times 4$  q-meshes for TaS<sub>3</sub> and TaSe<sub>3</sub> in the  $Pm-3n$  structure. We have calculated the superconducting  $T_c$  of Ta-O/S/Se compounds as estimated from the McMillan-Allen-Dynes formula:<sup>7-9</sup>

$$T_c = \frac{\omega_{log}}{1.2} \exp\left[-\frac{1.04(1 + \lambda)}{\lambda - \mu^* (1 + 0.62\lambda)}\right]$$

Here,  $\mu^*$  is the Coulomb pseudopotential ( $\mu^* = 0.1$ ). The electron-phonon coupling constant,  $\lambda$ , and the logarithmic average phonon frequency,  $\omega_{log}$ , were calculated by the Eliashberg spectral function for electron-phonon interaction:

$$\alpha^2F(\omega) = \frac{1}{N(E_F)} \sum_{kq,v} |g_{k,k+q,v}|^2 \delta(\varepsilon_k) \delta(\varepsilon_{k+q}) \delta(\omega - \omega_{q,v})$$

where  $\lambda = 2 \int d\omega \frac{\alpha^2F(\omega)}{\omega}$ ;  $\omega_{log} = \exp\left[\frac{2}{\lambda} \int \frac{d\omega}{\omega} \alpha^2F(\omega) \ln(\omega)\right]$ . Herein,  $N(E_F)$  is the electronic density of states at the Fermi level,  $\omega_{q,v}$  is the phonon frequency of mode  $v$  and wave vector  $q$ , and  $|g_{k,k+q,v}|$  is the electron-phonon matrix element between two electronic states with momenta  $k$  and  $k + q$  at the Fermi level.<sup>10, 11</sup>

## Supporting Figures

**Figure S0.** Comparison of the fitted Birch-Murnaghan equation of states for  $Pm-3n$  TaO<sub>3</sub> by using the calculated results with the PAW pseudopotentials and the full-potential LAPW methods.

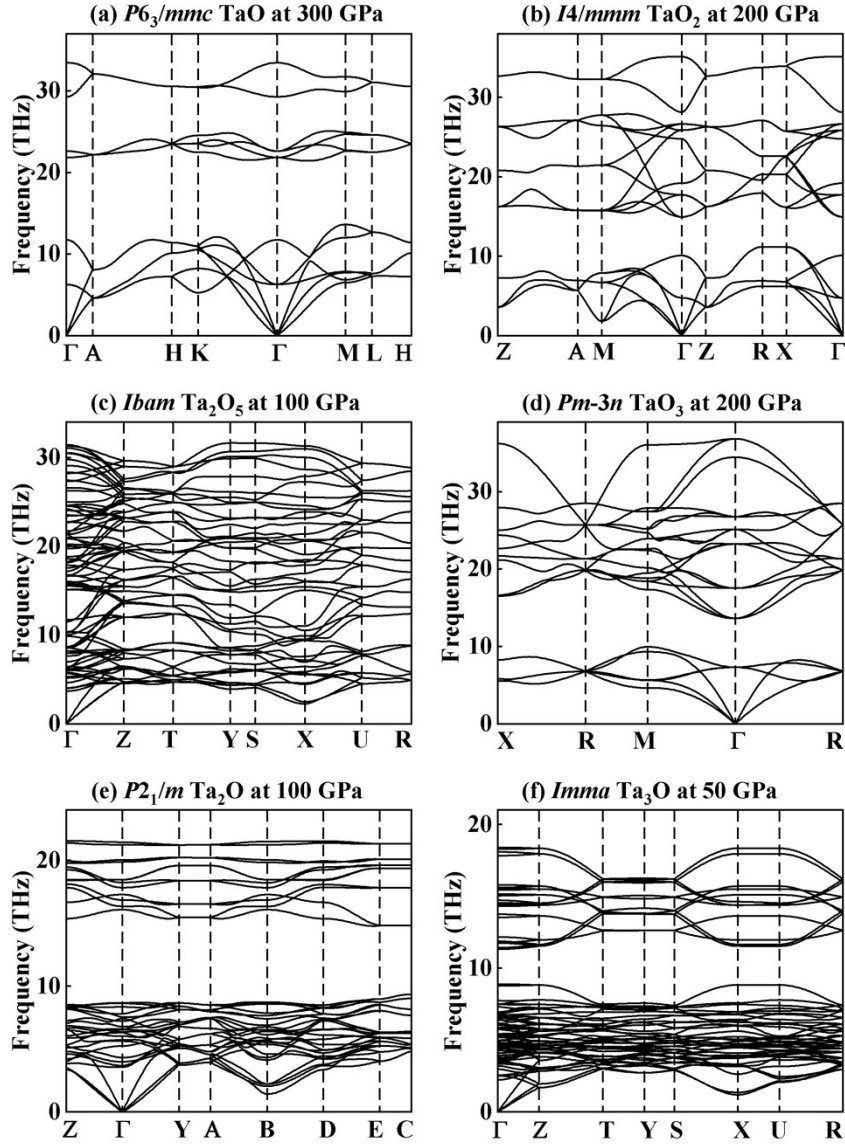

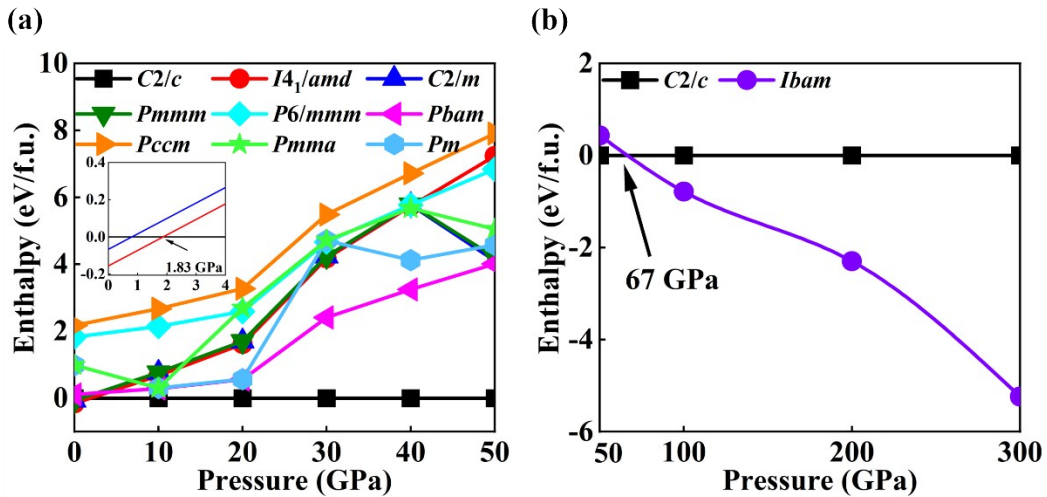

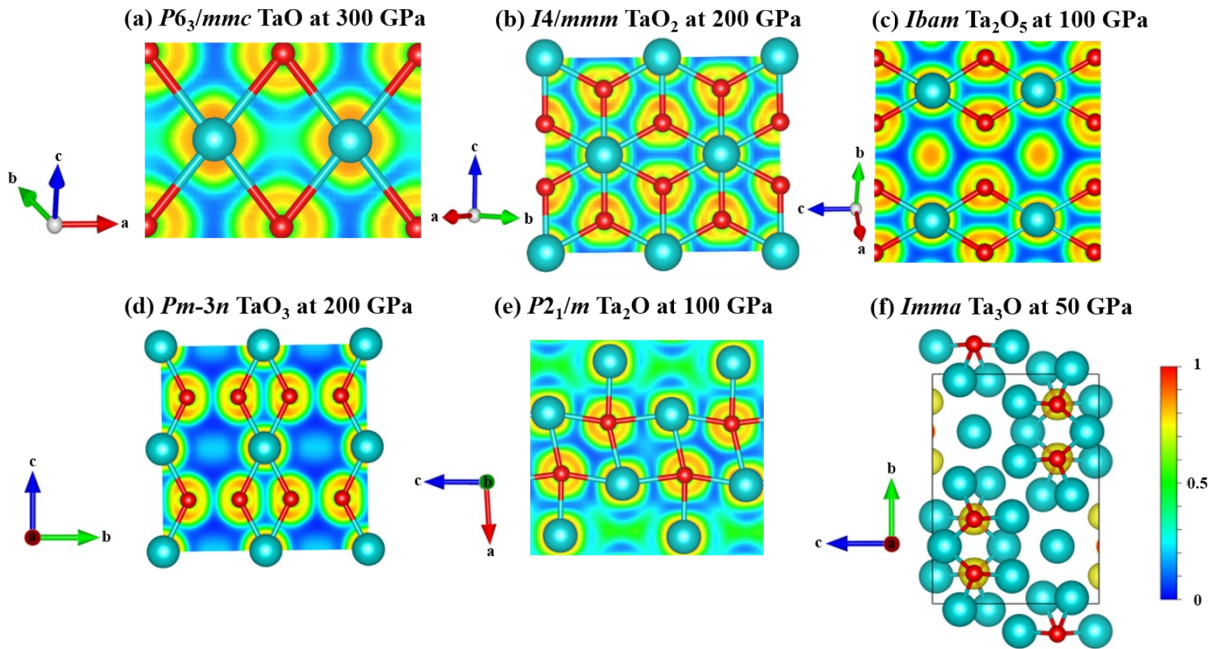

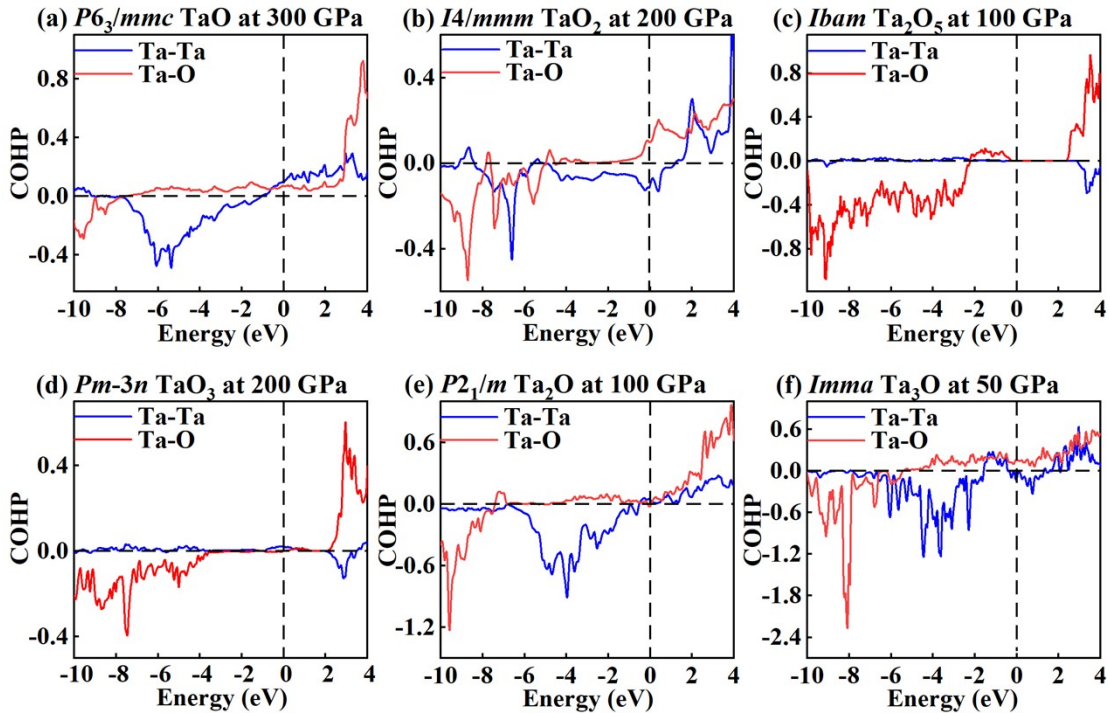

FIG. S1. Phonon dispersion curves of the stable Ta-O phases.

**FIG. S2.** Calculated enthalpy as a function of pressure for the reported<sup>12-19</sup> and predicted Ta<sub>2</sub>O<sub>5</sub> structures relative to the C2/c phase.

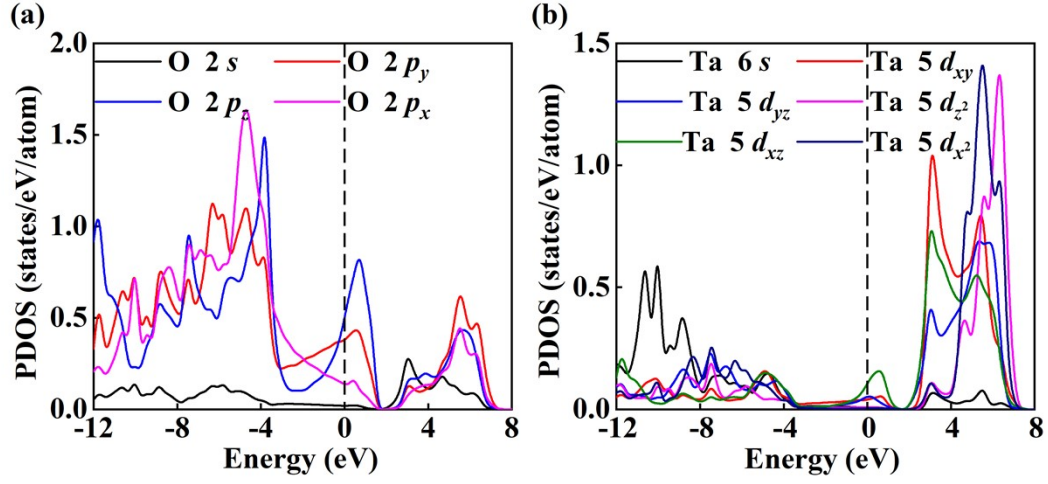

**FIG. S3.** Electron localization function (ELF) maps of the stable Ta-O phases. The ELF analysis can be used to distinguish different types of chemical bonding.

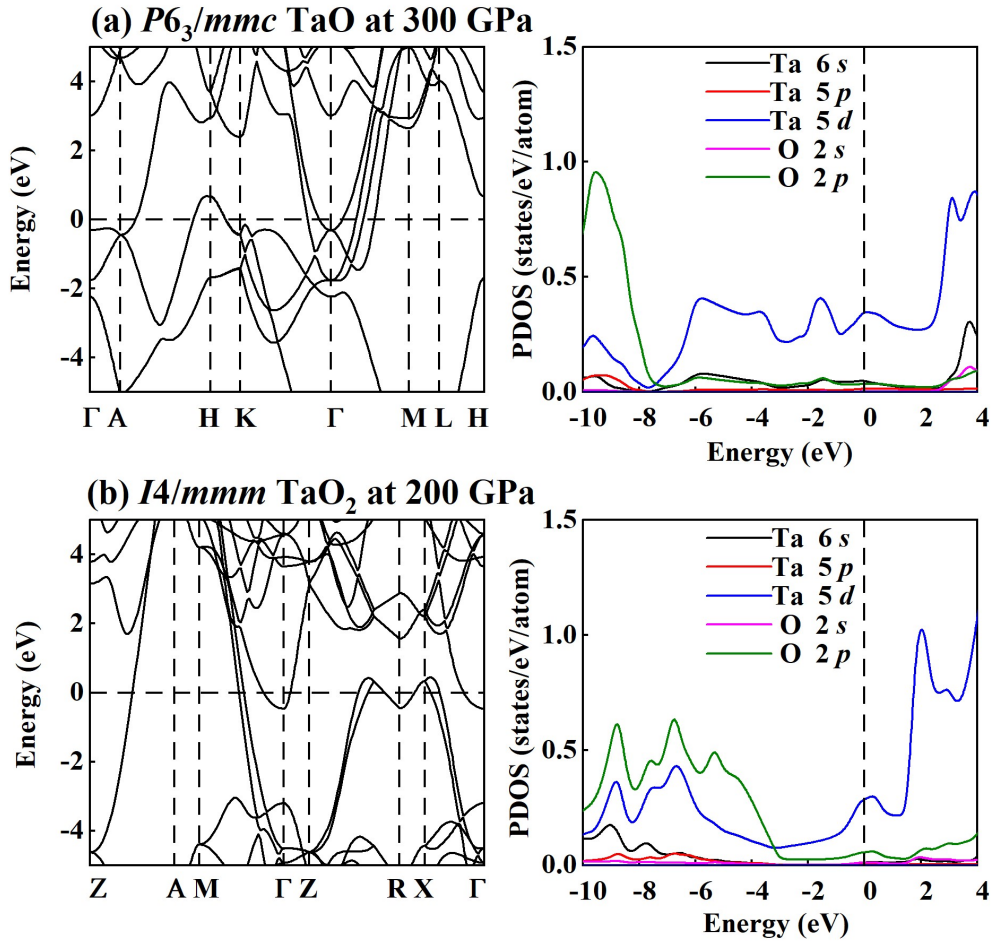

**FIG. S4.** The crystal orbital Hamiltonian population (COHP) of the Ta-O and Ta-Ta interactions in stable Ta-O compounds. Generally, negative COHP values indicate bonding states, while positive COHP values indicate antibonding states.

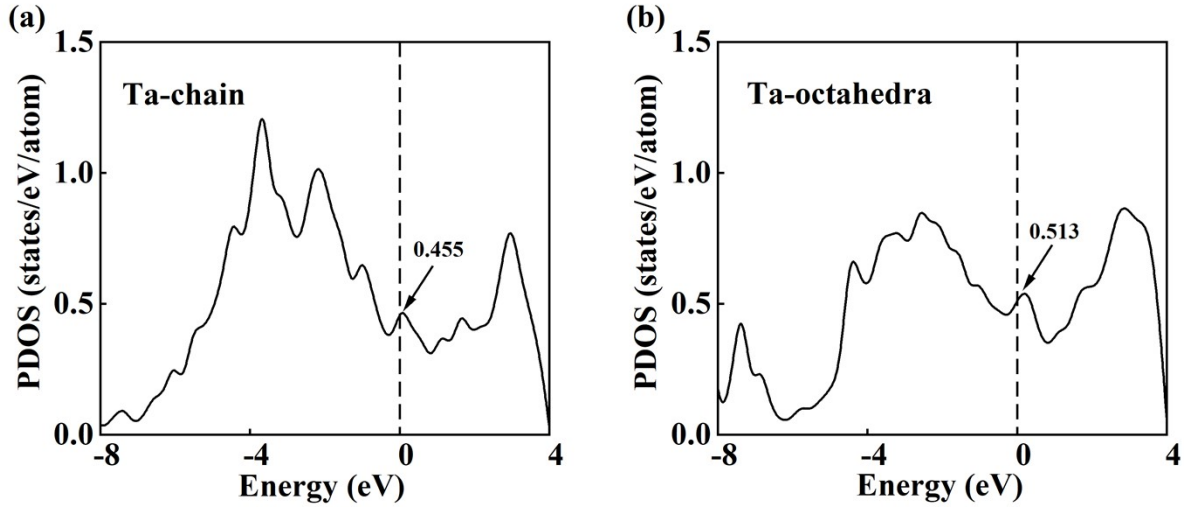

**FIG. S5.** Projected density of states (PDOS) associated to the (a) O 2s and 2p orbitals, and (b) Ta 6s and 5d orbitals in  $Pm\text{-}3n$  TaO<sub>3</sub> at 200 GPa.

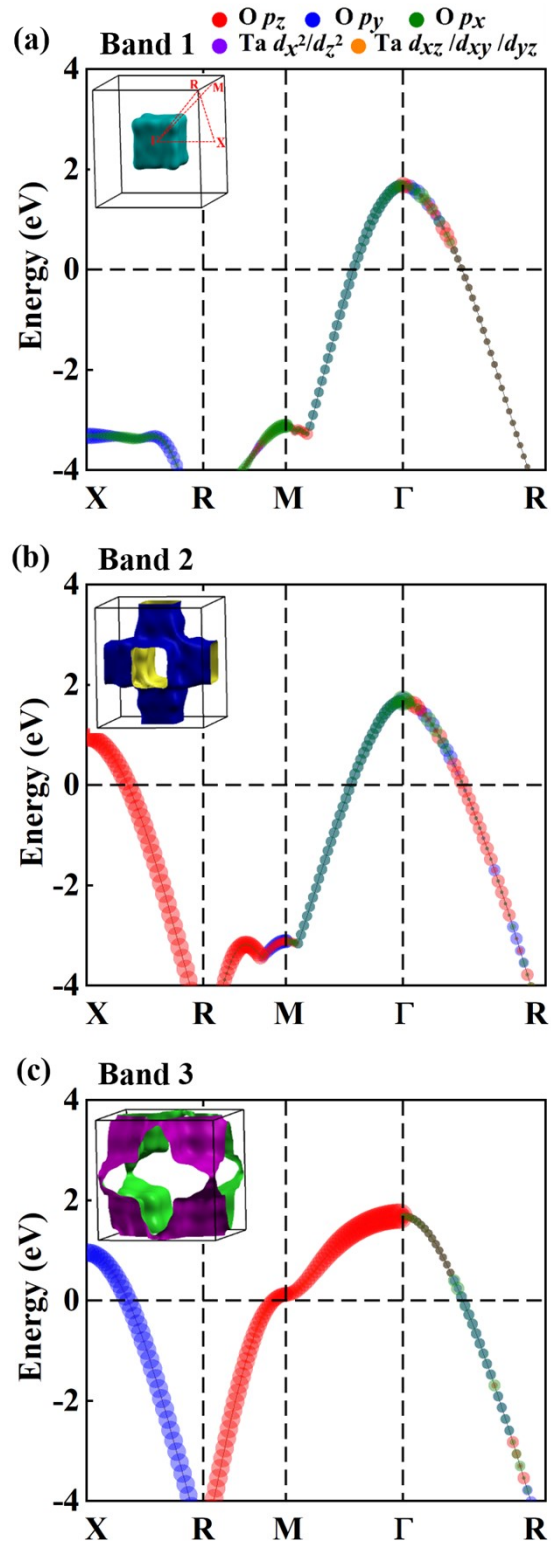

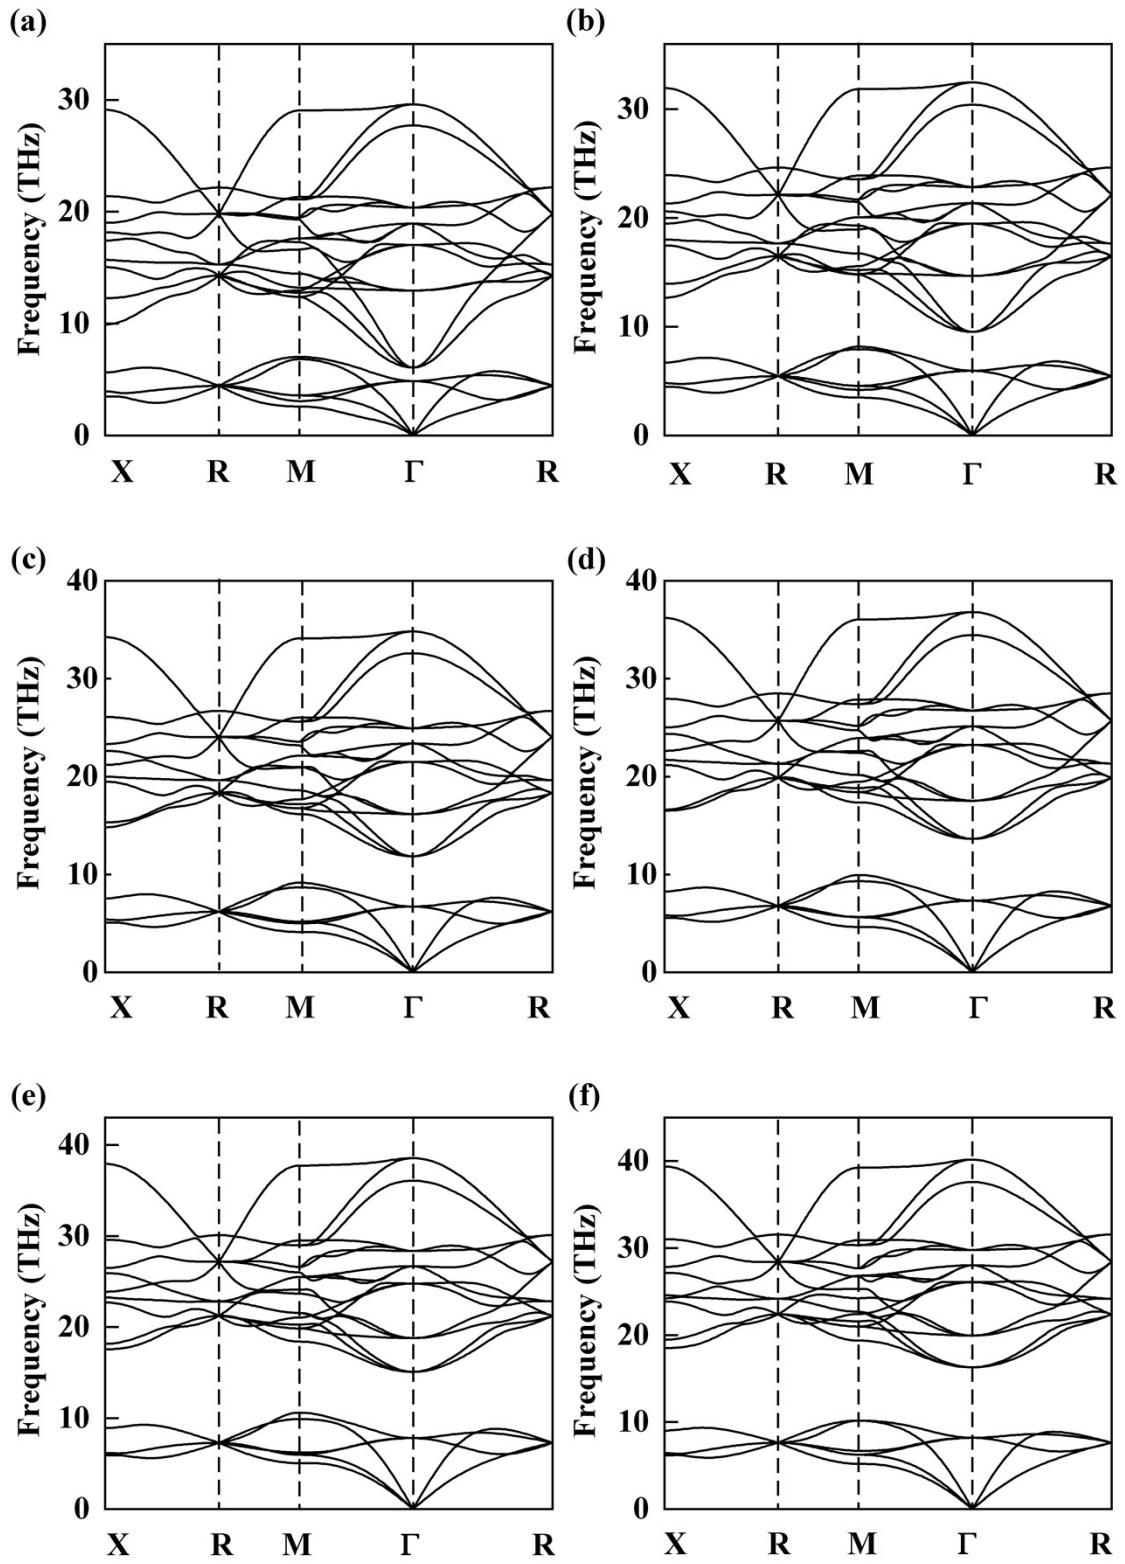

**FIG. S7.** PDOS of (a) Ta atom forming a linear atomic chain, and (b) Ta atom located in the octahedra in *Imma* Ta<sub>3</sub>O at 50 GPa

The electronic density of states (DOS) of the Ta atom forming a linear atomic chain is 0.455 states/eV/atom at the Fermi level, while the DOS of the Ta atom located in the Ta-O octahedra is 0.513 states/eV/atom, showing a greater contribution to the metallicity of Ta<sub>3</sub>O.

**FIG. S8.** The first, second, and third bands of  $Pm-3n$  TaO<sub>3</sub> passing through the  $E_F$  at 200 GPa.

**FIG. S9.** Phonon dispersion curves of  $Pm-3n$  TaO<sub>3</sub> at (a) 50, (b) 100, (c) 150, (d) 200, (e) 250, and (f) 300 GPa.

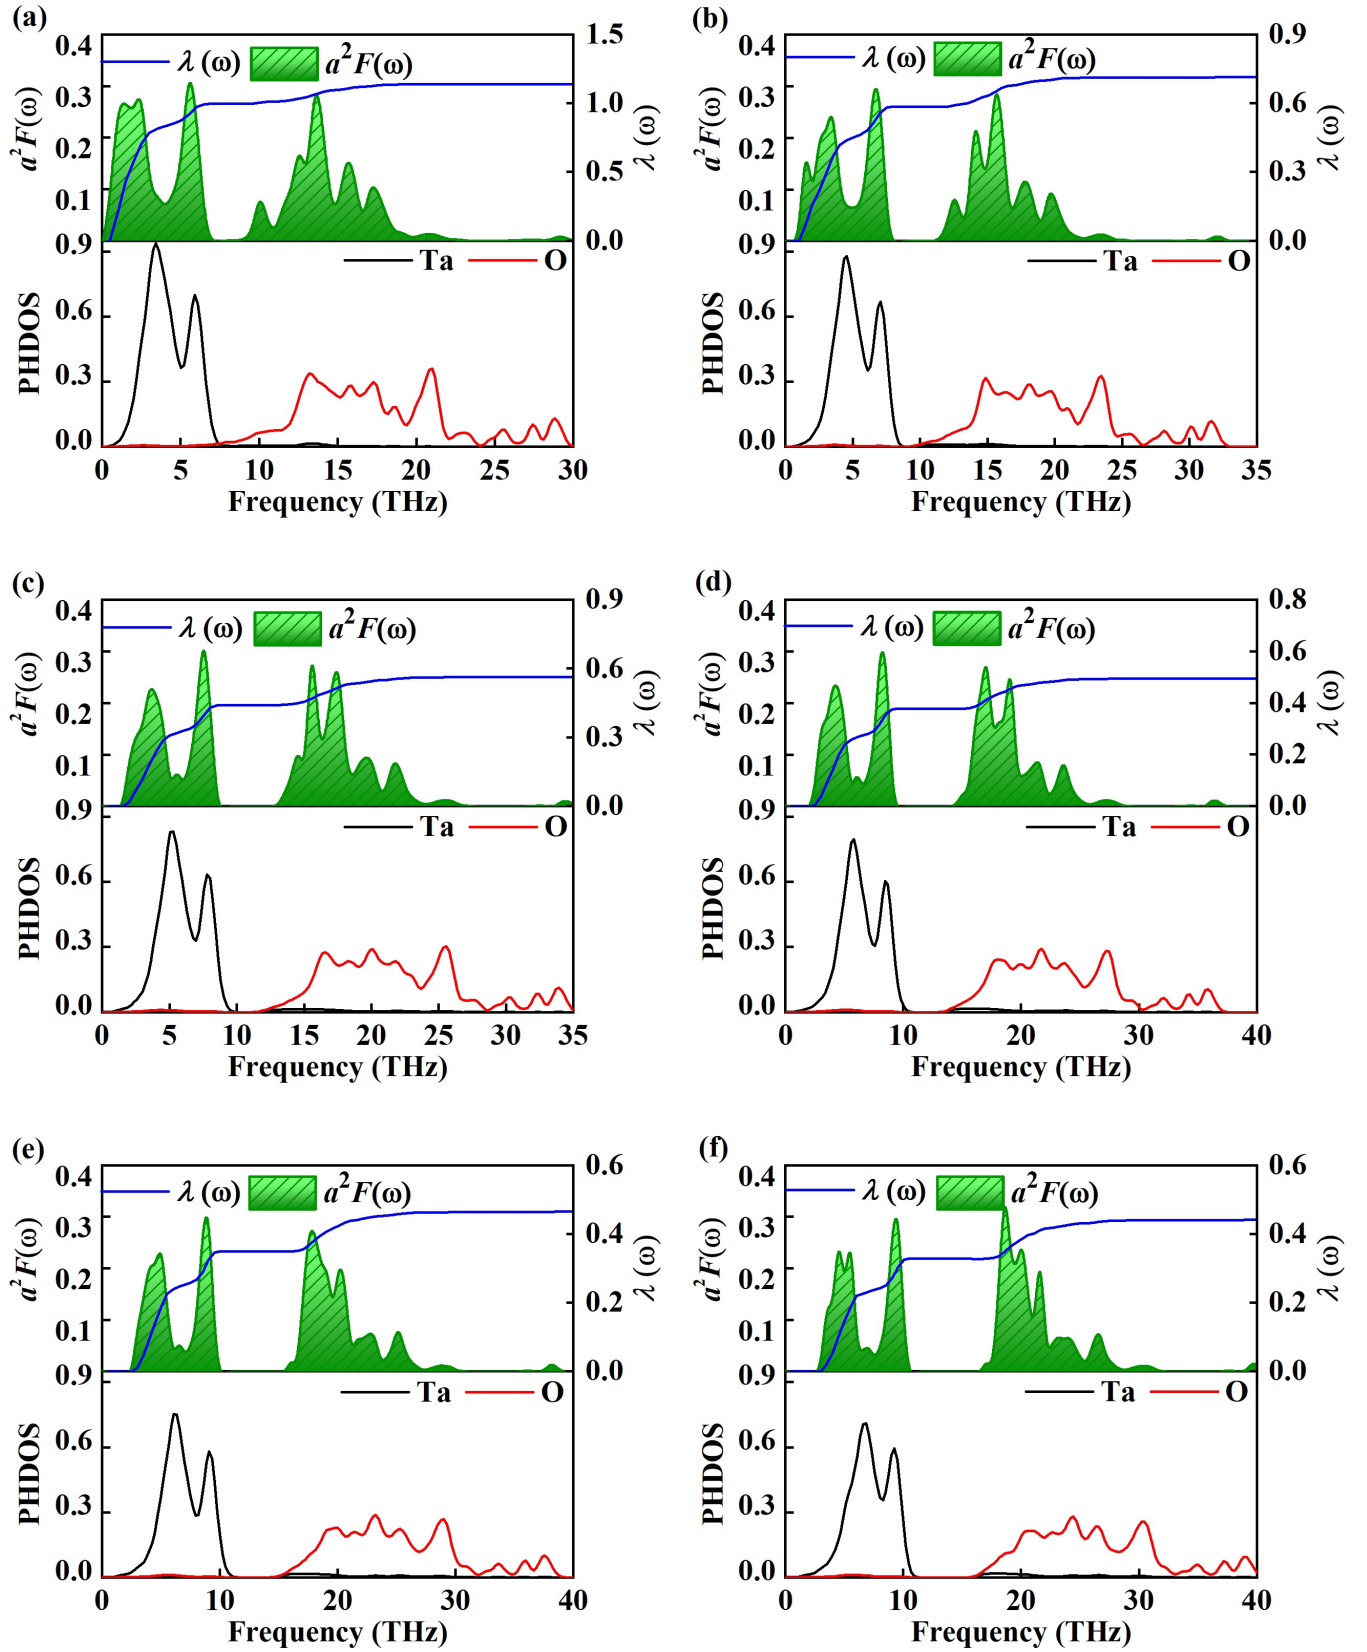

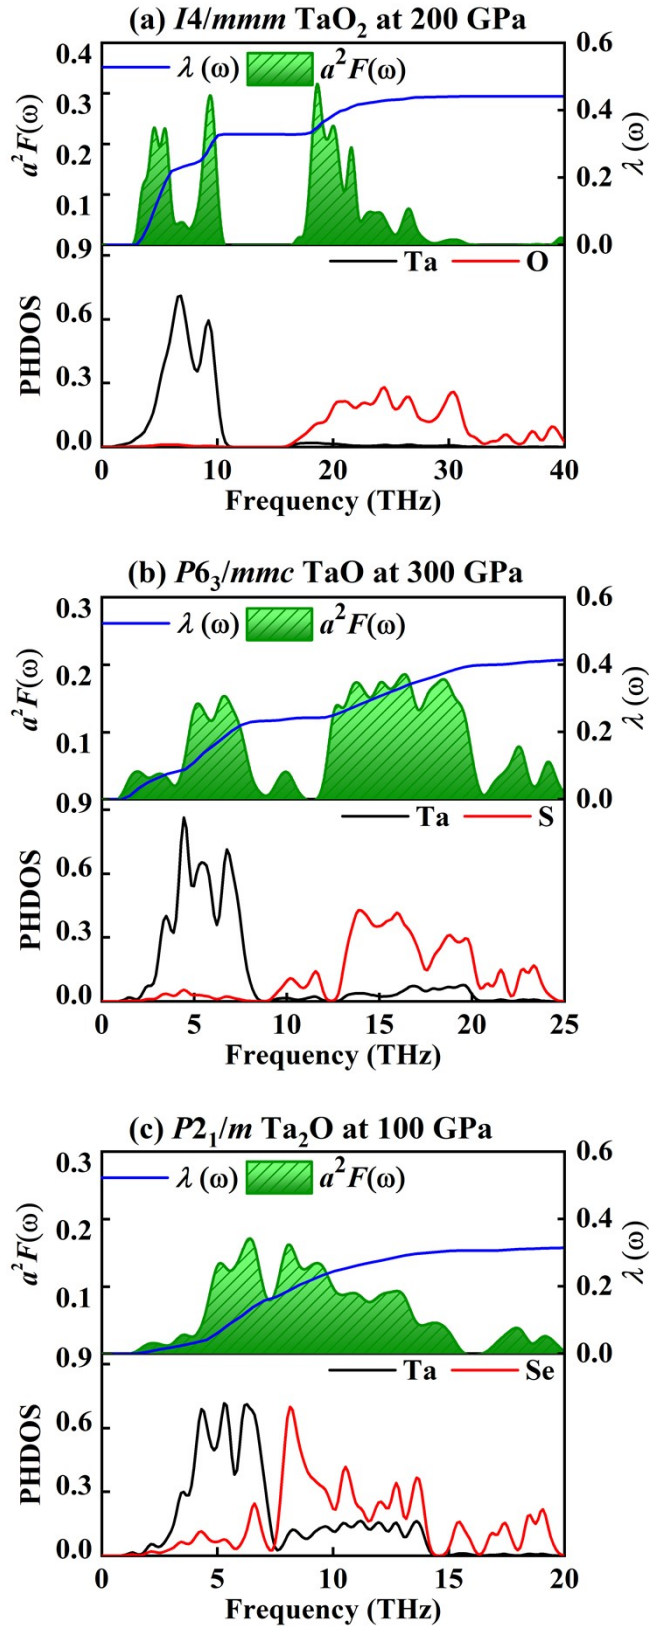

FIG. S10. The projected phonon densities of states (PHDOS) and Eliashberg spectral function of  $Pm-3n$  TaO<sub>3</sub> (a) 50, (b) 100, (c) 150, (d) 200, (e) 250, and (f) 300 GPa.

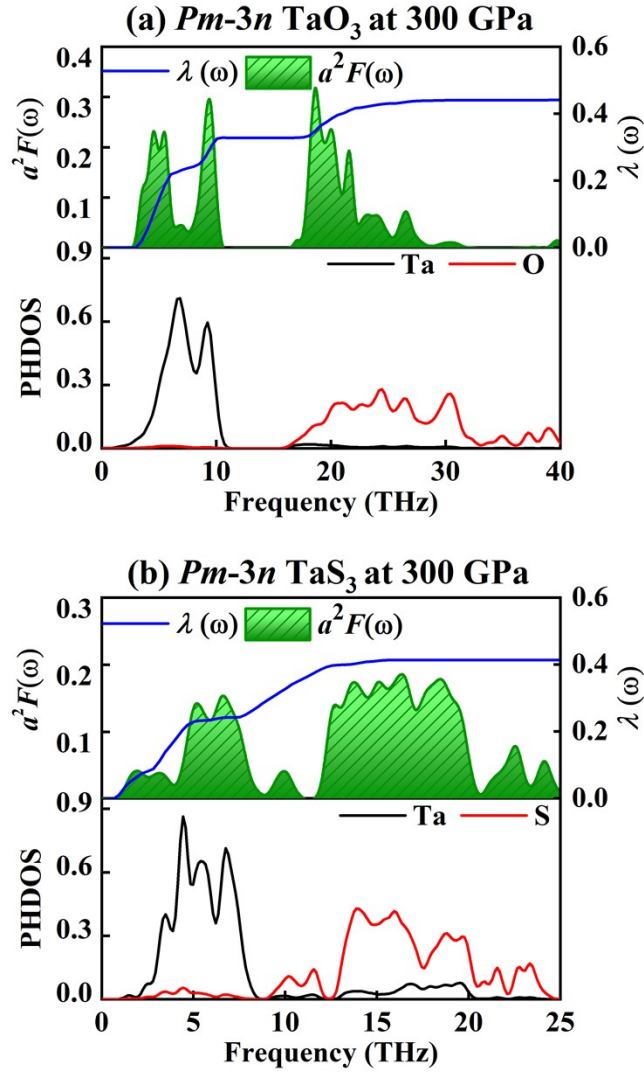

**FIG. S11.** The PHDOS and Eliashberg spectral functions of (a)  $I4/mmm$  TaO<sub>2</sub> at 200 GPa, (b)  $P6_3/mmc$  TaO at 300 GPa, and (c)  $P2_1/m$  Ta<sub>2</sub>O at 100 GPa.

**FIG. S12.** The ELF maps of (a)  $Pm-3n$   $TaS_3$  and (b)  $Pm-3n$   $TaSe_3$  at 300 GPa. Golden, yellow, and green spheres represent Ta, S, and Se atoms, respectively.

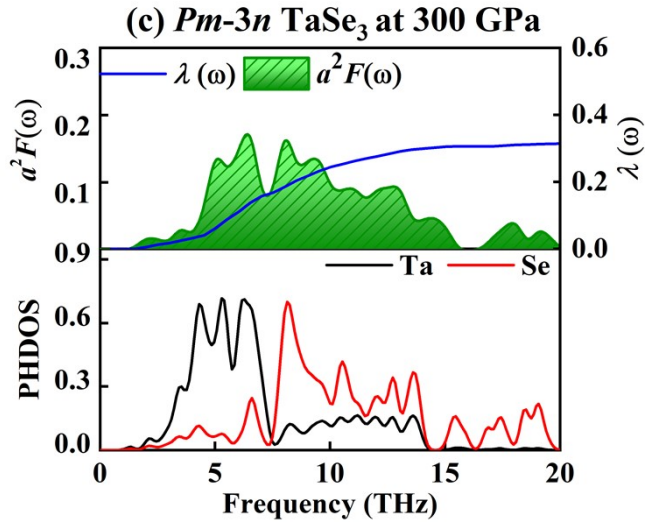

FIG. S13. The PHDOS and Eliashberg spectral functions of *Pm-3n* TaX<sub>3</sub> (*X* = O, S, and Se) at 300 GPa.

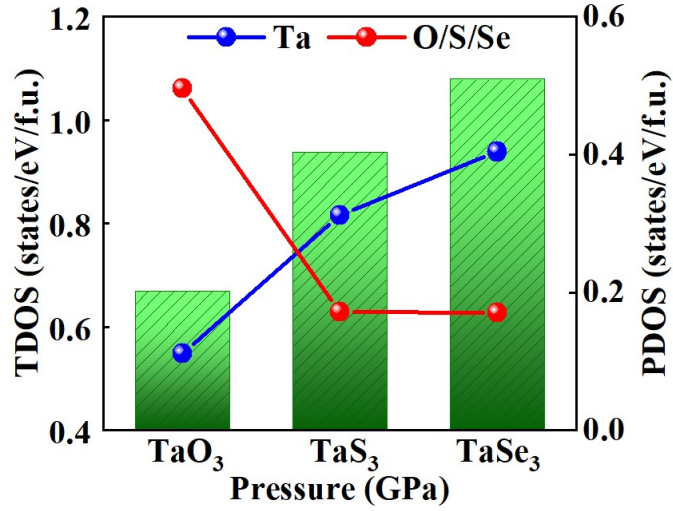

FIG. S14. The total DOS and PDOS of *Pm-3n* TaX<sub>3</sub> (*X* = O, S, and Se) at 300 GPa.

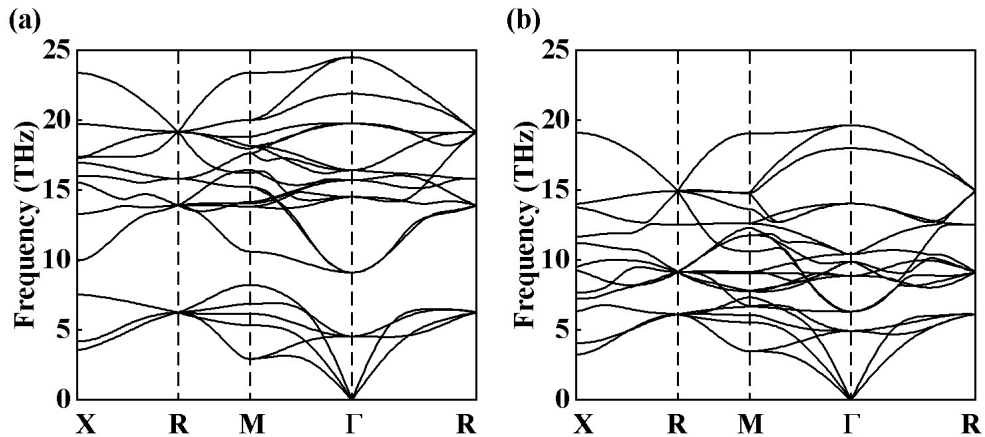

FIG. S15. Phonon dispersion curves of *Pm-3n* TaS<sub>3</sub> and TaSe<sub>3</sub> at 300 GPa.

**FIG. S16.** The ELF maps of *Ibam* Ta<sub>2</sub>O<sub>5</sub> at (a) 67, (b) 100, (c) 150, (d) 200, (e) 250, and (f) 300 GPa.
