## $\dagger$ Discriminatory Fluorescence and FRET in ChiralPerovskite/RhB system

## Materials

Cesium carbonate ( $\mathrm{Cs}_{2} \mathrm{CO}_{3}$, 99.9\%), lead (II) bromide ( $\mathrm{PbBr}_{2}, 99 \%$ ), oleyl amine (OAm, $80 \%-90 \%$ ), oleic acid (OAc, 85\%), N, N-dimethylformamide (DMF, anhydrous, 99.8\%), octadecene (ODE, 90\%), $S$ - and $R$ - $\alpha$-methylbenzenemethanamine ( $S$ - and $R$-MBA, 99\%), hexane (97\%), Rhodamine B (RhB, 99\%) were purchased from Shanghai Aladdin Biotechnology. Acetone (AR) and toluene (AR) were purchased from Tianjin Yuanli Chemical Co., Ltd. Methyl acetate (MeOAc, 99\%, AR) was purchased from Shanghai Macklin Biochemical Co., Ltd. CdSe/ZnS QDs was purchased from Suzhou Xingshuo Nanotech Co. Ltd. All materials were used as received without further purification.

## Experimental Procedure

Synthesis of $\mathrm{CsPbBr}_{3}$ nanowires (NWs)
Perovskite NWs were synthesized according to the literature. ${ }^{1}$ To a solution of ODE $(1.25 \mathrm{~mL})$, OAc ( 0.125 mL ), and OAm ( 0.125 mL ), 0.1 mL of Cs-OA precursor ( 0.102 g of $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ degassed in 5 mL of ODE and 0.3 mL of OA at $150{ }^{\circ} \mathrm{C}$ ) and 0.2 mL of $\mathrm{PbBr}_{2}$ precursor ( $0.4 \mathrm{M}, 147 \mathrm{mg} \mathrm{PbBr} 2$ in 1 mL of DMF) were swiftly injected. After $10 \mathrm{~s}, 5 \mathrm{~mL}$ of acetone was swiftly added to quench the reaction. The NWs was precipitated by centrifugation at 3500 rpm for 5 min and then redispersed in toluene.

Preparation of chiral perovskite nanowires (CPNWs)
A certain amount of chiral ammonium salt methyl acetate solution was added to the initial NWs solution, the molar ratio of the ammonium salt and the initial $\mathrm{CsPbBr}_{3} \mathrm{NWs}$ is 0.2 . The mixture was centrifuged for 5 min at 12500 rpm , then the precipitate is collected and dispersed in toluene to obtain the CPNWs.

Preparation of chiral perovskite nanowires and organic molecule hybrid system
The $\mathrm{RhB}(9.58 \mathrm{mg}, 20 \mathrm{mmol})$ is dissolved in 1 mL acetonitrile, and then the RhB solution with various amounts were added to the chiral CPNWs dispersion in toluene ( $500 \mu \mathrm{~L}$ ) to afford the donor-acceptor mixtures.

## Preparation of chiral perovskite nanowires and cadmium selenide quantum dots system

The different volume of CdSe NCs were added to the chiral CPNWs dispersion in toluene ( 1 mL ) to afford the CPNWs donor-CdSe acceptor mixtures for time-resolved fluorescence measurements, and different volume of CdSe NCs were added to the chiral CPNWs dispersion in toluene $(500 \mu \mathrm{~L})$ to measure the CD and CPL spectra.

## Detailed calculation formula for $\boldsymbol{\Phi}_{\mathrm{ET}}$

Energy transfer efficiency is typically calculated using the relative fluorescence lifetime $(\tau)$ of the donor in the absence and presence of the acceptor. ${ }^{2}$
$\Phi_{E T}=1-\tau_{\text {Donor }- \text { Acceptor }} / \tau_{\text {Donor }}$
where $\tau_{\text {Donor-Acceptor }}$ is refers to the lifetime of the donor (CPNWs) and acceptor (RhB) mixture; $\tau$ Donor is the lifetime in which only the donor exists. The energy transfer efficiency calculated is shown in Fig. S2.

## Double reciprocal analysis of $K_{\text {app }}$

Double reciprocal analysis of fluorescence quenching data is carried out to estimate the association between the RhB and CPNWs. ${ }^{3,4}$

The equilibrium between the quencher $(Q)$ and the emissive species $(E)$ is assumed to involve the formation of a complex, where all species exist in both uncomplexed and complexed states. This equilibrium is governed by an apparent association constant, denoted as $K_{\text {app }} .{ }^{5}$
$Q+E \stackrel{K_{\text {app }}}{\leftrightharpoons} Q-E$
Then, it is assumed that the fluorescence intensity $\left(\Phi_{f}\right)$ is considered to be directly proportional to the fluorescence quantum yield ( $\Phi_{\text {PLQY }}$ ). This assumption is rational as long as there are no complicating factors such as self-absorption or high scattering, indicated by the low absorbance and low turbidity. ${ }^{6}$

The observed fluorescence quantum yield (or fluorescence intensity, mentioned above), denoted as $\Phi_{f, o b s}$, is related to the fluorescence yields of the uncomplexed species $\left(\Phi_{f}^{0}\right)$ and the complexed species $\left(\Phi^{\prime}\right)$ through a degree of association $\alpha$ :

$$
\Phi_{f, o b s}=(1-\alpha) \Phi_{f}^{0} \times(\alpha) \Phi_{f}^{\prime}
$$

At relatively high concentrations " $\alpha$ " can be equated to ( $\left.K_{\text {app }}[\mathrm{Q}]\right) /\left(1+K_{\text {app }}[\mathrm{Q}]\right.$ ), which can be simplified to
$\frac{1}{\Phi_{f}^{0}-\Phi_{f, o b s}}=\frac{1}{\Phi_{f}^{0}-\Phi_{f}^{\prime}}+\frac{1}{K_{a p p}\left(\Phi_{f}^{0}-\Phi_{f}^{\prime}\right)[Q]}$
the given equation is in the form of $y=m x+b$ represents a linear relationship between the variables y and x . Therefore, if the quencher and emitter form a complex as described by the first equation, suggest that there should be a linear relationship can be observed for $\frac{1}{\Phi_{f}^{0}-\Phi_{f, o b s} \text { graphed vs. } \frac{1}{[Q]} .}$

Accordingly, the correlation constant ( $K_{\text {app }}$ ) between CPNWs and RhB is estimated to be $8.1 \times 10^{4} \mathrm{M}^{-1}$ (Fig. S3a). Post a diurnal interval the $K_{\text {app }}$ between CPNWs and RhB is determined to be $5.8 \times 10^{4} \mathrm{M}^{-1}$ (Fig. S3b).

## Characterizations

Ultraviolet-visible (UV-Vis) absorptions spectroscopy measurements of CPNWs and RhB

The UV-vis absorption spectra were recorded on a MAPADA UV-1800PC spectrometer.
Photoluminescence (PL), PL excitation (PLE) spectroscopy and Time-resolved Photoluminescence (PL Decay) measurements

The PL spectra and PL Decay were recorded by a Horiba Fluorolog system (HoribaF4600) with an Xe lamp as the excitation source and a Quanta-Phi integrating sphere.

## X-ray diffraction (XRD) measurements

The XRD spectra were measured with the XRD Bruker D8-focus with a Cu Ka ( $\lambda=1.5406$ $\mathrm{A}^{\circ}$ ) radiation source.

Transmission electron microscopy (TEM) measurements
The TEM images were recorded on a TEM (JEM 2100F) at 200 kV . The samples for measurements were suspended on carbon-coated Cu grids.

Circular dichroism (CD) and circularly polarized light (CPL) measurements

The CD spectra were measured by a Jasco J-1700 CD spectrometer. The CPL spectra were measured on a circularly polarization fluorescence spectrometer (JASCO CPL200)

## Supporting Figures and Tables

Figure S1. (a) PLE spectra of RhB and CPNWs-RhB mixture, reference absorption spectra of CPNWs; (b) Time-resolved fluorescence spectra of CPNWs-RhB with different excitation wavelengths.

Figure S2. Energy transfer efficiency as a function of RhB concentration obtained by time-resolved fluorescence spectra decay experiments after mixed (a) and aged for one day (b).

Figure S3. Double-reciprocal analysis of the CPNWs PL quenching data after mixed (a) and aged for one day (b).

Figure S4. (a) PL spectra and absorption spectra of RhB; (b) CD spectra of RhB and RhB-chiral salts mixture.

Figure S5. CD spectra of CPNWs with different amount of RhB (a) and enlarged CD spectrum of 520 nm-620 nm (b), CPL spectra of CPNWs with different amount of RhB (c).

Table S1: Fitting parameters of the PL decay of the CPNWs-RhB mixtures monitored at 480 nm .

| Sample | $\mathrm{A}_{1}$ (\%) | $\tau_{1}(\mathrm{~ns})$ | $\mathrm{A}_{2}$ (\%) | $\tau_{2}(\mathrm{~ns})$ | $\tau_{\text {avg }}(\mathrm{ns})$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CPNWs+0 $\mu \mathrm{M}$ RhB | 46.67 | 6.69 | 53.33 | 35.60 | 31.52 |
| CPNWs+0.5 $\mu \mathrm{M}$ RhB | 58.46 | 5.99 | 41.54 | 33.84 | 28.29 |
