Section S1: Reduction to the cardanol diene

After the inclusion of dispersion, solvation, and thermodynamic corrections, **TS9–10** is lower in free energy than the intermediate **9** that it connects to. Several studies,^{1–8} including some most recent ones,^{9–18} report such submerged transition states, where geometry optimisations and energy refinements are performed at different levels of theory. Such transition states are, in fact, artifacts of the lower level of theory employed in the optimisation. In these cases, the transition states, and the intermediates below which they fall probably would cease to be proper stationary points at the higher level of theory. They would rather denote non-equilibrium structures along a continuous reaction pathway as they might be expected to be visited along with an IRC at the higher level (if that were practicable to trace). Such “vanishing” transition states and intermediates might safely be omitted from the final profiles, but we kept them on the energy profile in the main text for illustrative purposes (to follow the transformations that take place).

Table S3. Section S2: Reduction to the cardanol monoene

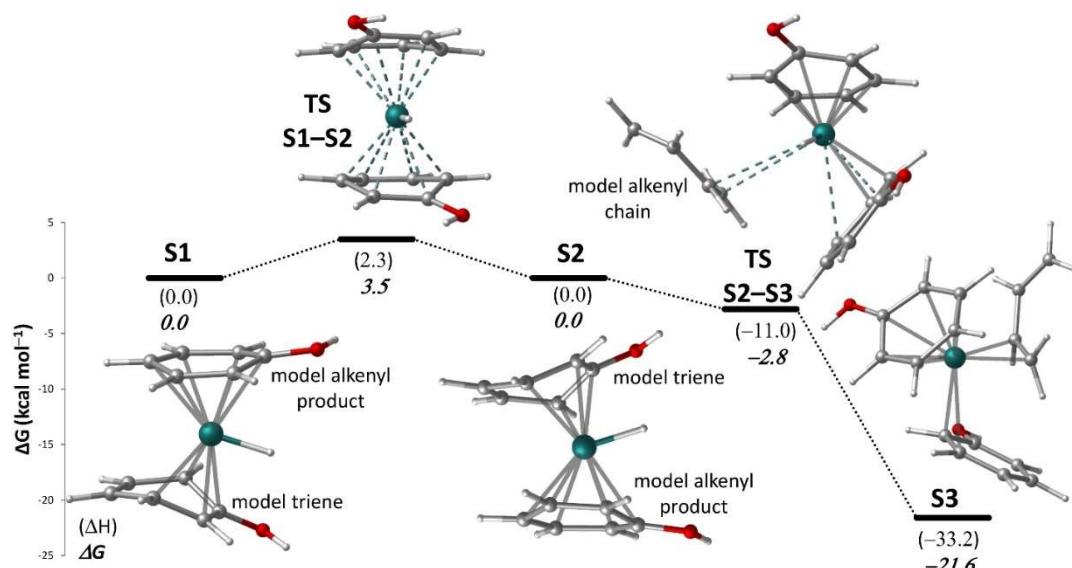

There is a facile hydride transfer to C_(SP2)#12, where Ru forms a η^1- coordination with C#11 and an agostic interaction with the H on C#12 ($\Delta G_{11 \rightarrow 12} = -1.2 \text{ kcal mol}^{-1}$ and $\Delta G^\ddagger_{11 \rightarrow 12} = 1.6 \text{ kcal mol}^{-1}$, see Scheme 7 in the main text). iPrOH is still coordinated to Ru in intermediate **12**. The next step is kinetically demanding with a barrier of 17.1 kcal mol⁻¹, where Ru forms a β -agostic interaction with the hydrogen of C#10 at first. Although in the transition state, **TS12–13**, iPrOH is coordinated to the Ru metal, it eventually rearranges to form a hydrogen bond with the –OH of phenol in the resulting optimised complex, **13** ($\Delta G_{12 \rightarrow 13} = 6.7 \text{ kcal mol}^{-1}$ and $\Delta G^\ddagger_{12 \rightarrow 13} = 17.1 \text{ kcal mol}^{-1}$). Again, followed by a low kinetic barrier via **TS13–14**, intermediate **14'** is formed, where the β -agostic interaction between the hydrogen at C#10 is lost ($\Delta G_{13 \rightarrow 14'} = -9.4 \text{ kcal mol}^{-1}$ and $\Delta G^\ddagger_{13 \rightarrow 14'} = 0.5 \text{ kcal mol}^{-1}$). However, it is still a β -agostic intermediate, with agostic interaction at C#12 (see Scheme 7 in the main text).

In intermediate **14'**, the hydride bonded to Ru is facing toward C#10. To initiate the reduction to the monoene, however, this hydride needs to be transferred to C#11. We therefore modelled another isomer of **14'**, i.e., **14**, where now Ru–H is positioned towards C#11 ($\Delta G_{13 \rightarrow 14} = 8.9 \text{ kcal mol}^{-1}$, see Scheme 8 in the main text). For the hydrogen transfer to C#11, a transition state, **TS14–15**, is associated with a kinetic barrier of 6.7 kcal mol⁻¹, which gives rise to intermediate **15'** ($\Delta G_{14 \rightarrow 15'} = -4.0 \text{ kcal mol}^{-1}$ and $\Delta G^\ddagger_{14 \rightarrow 15} = 6.7 \text{ kcal mol}^{-1}$). In **15'**, there is a β -agostic interaction between Ru–H and C#11, which when broken gives rise to η^3 -allyl complex, **15**.

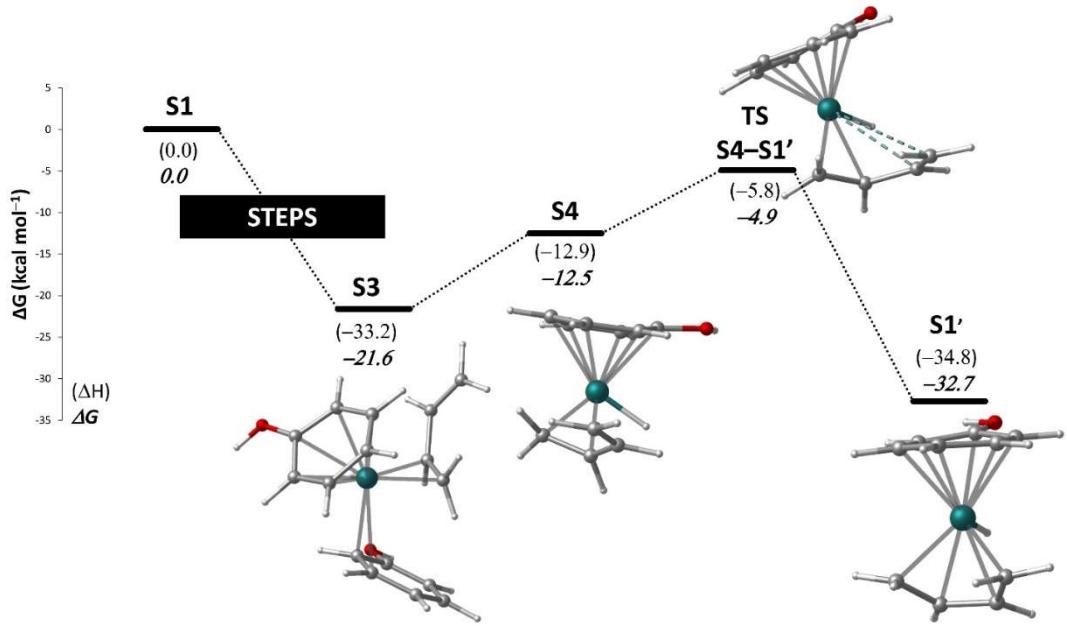

Section S3: Model studies for associative interchange mechanism

In these model studies, we have used a truncated system with phenol and 1,3-butadiene. Since we are doing these model studies to see the kinetics involved in the product exchange with fresh triene, and; therefore, phenol with 1,3-butadiene precisely illustrates the formation of model complex **1**. However, such a model system does not count the steric effects, making some intermediates much more stable than the actual system.

We start the reaction profile with a model intermediate **S1**, where the “model alkenyl product” is still associated, whereas the new reactant, illustrated as “model triene,” is associated via η^4 -coordination. **TS-S1–S2** allows interchanging η^6 - and η^4 -coordination of the “model alkenyl product” and “model triene.” Via the next low kinetic barrier, the **S3** intermediate is obtained with a η^2 -coordinated “model alkenyl product” and η^2 -coordinated “model alkenyl chain.” **S3** seems to be a very stable intermediate; however, it is missing the steric effects from the actual alkenyl chain in the actual system. Even if we agree on the stability of **S3**, the next kinetic barrier via **TS-S4–S1'** of 16.7 kcal mol⁻¹ is much lower than the overall barrier, 29.2 kcal mol⁻¹, for reduction to the cardanol monoene product, which eventually gives the **S1'** intermediate comparable to our proposed entry (complex **1**) into the catalytic cycle (Schemes S1 and S2).

Scheme S1. Model studies for associative interchange mechanism (B3PW91-D3BJ/ECP2/PCM level, *iPrOH* as the model solvent). Energies (ΔH and ΔG) are in kcal mol⁻¹ relative to **S1**. Table S5 shows the reaction energies of individual steps.

Scheme S2. Model studies for associative interchange mechanism (B3PW91-D3BJ/ECP2/PCM level, *i*PrOH as the model solvent). Energies (ΔH and ΔG) are in kcal mol⁻¹ relative to **S1**. Table S5 shows the reaction energies of individual steps.

Section S4: Derivation of the pressure correction

The use of elevated pressure in the expressions for evaluating the thermodynamic corrections from the partition function of an ideal gas only affects the translational part of the entropy (and therefore only affects the computed free energies when the number of particles changes along a reaction step). The rationale for this comes from the restricted translational degrees of freedom in a condensed phase compared to the gas phase. The derivation of the correctional term for the solvent, *i*PrOH, is shown below:

$$p = \frac{\rho RT}{M} = 381.0 \text{ atm},$$

where, p = *i*PrOH pressure, ρ = density of *i*PrOH (0.786 g/cm³), M = molar mass of *i*PrOH (60.1 g/mol), T = 355.65 K, p° = 1 atm, R = ideal gas constant (8.314 J/K.mol).
