1. Materials and general methods

All the chemicals were obtained from commercial sources, and used without further purification. Carbon black, and N-methyl pyrrolidine (NMP) were procured from Alfa Aesar, and Nafion solution (5 wt. %) was procured from Sigma Aldrich. The commercially available H_2O_2, 30% w/v, procured from Alfa Aesar, was used to perform the experiments. The solvents required for synthesis, and conducting CV measurements were dried and distilled using standard techniques. *9-hydroxy-1H-phenalen-1-one* was prepared using the literature method.[1]

Crystals suitable for single crystal X-ray diffractions (SCXRD) were loaded on a Bruker Smart Apex CCD diffractometer at 100 K. All the structures were solved by direct methods using SHELXS-97 and refined by full-matrix least squares on F^2 using SHELXL-97 softwares.[2] The details of crystallographic refinement parameters is given in Table S1. Anisotropic displacement parameters are used to refine the non-hydrogen atoms. All the hydrogen atoms were included in idealized positions, and were refined isotropically by a riding model.

The cyclic voltammetric (CV) tests were performed using a three-electrode assembly; glassy carbon (GC) working electrode, Pt counter electrode, and Ag/AgCl (3.0 M KCl) reference electrode. The electrochemical studies of complex **1** with CV were conducted in 10 ml DMF solution of complex **1** (1 mM) and the supporting electrolyte, tetrabutylammonium hexafluorophosphate (0.1 M). The CV measurements were carried out under an oxygen-free atmosphere by purging nitrogen gas, and the scan rate was fixed at 50 mV s^{-1}. To test H_2O_2 fuel cell activity, the modified GC electrode and Ni foam anode were immersed in the supporting electrolyte for at least 5 min before adding H_2O_2 to the electrolytic solution. The performance tests are repeated at least 5 times to ensure the reproducibility.

2. Crystallographic data for the hmbh-PLYH_2 ligand and complex 1.

Table S1. Crystal data and structure refinement parameters for the ligand, hmbh-PLYH_2 and complex **1**.

Identification code	hmbh-PLYH_2	Complex **1**

9. DFT calculations

The optimized geometry parameters around the metal centre of the distorted octahedral complex **1** in its high spin (S = 5) and broken symmetry spin states are presented in Table S4 along with respective experimental X-ray values for comparison. The DFT calculated bond distance and bond angle values obtained at method 1 (B3LYP/def2-SVP), method 2 (B3LYP+D3BJ/def2-SVP+def2-TZVP), method 3 (BP86+D3BJ/def2-SVP+def2-TZVP) are in good accord with the X-ray values with mean absolute deviation for bond distance values are estimated as 0.031, 0.028, 0.031 Å. The method 2 is selected for the present study. Note that, the metal ions are treated with def2-TZVP basis function during optimization.

Broken symmetry analysis is performed for **1** to **1**$^{-4}$ complexes. The magnetic coupling constant (J) is obtained using eq.

$$J = - \frac{(E_{HS} - E_{BS})}{\langle S_{max}^{2} \rangle - \langle S_{min}^{2} \rangle}$$

Where, $(E_{HS} - E_{BS})$ is the energy difference between is high spin (HS) and broken symmetry (BS) spin states and S_{max}^{2}, S_{min}^{2} are maximum and minimum magnetic spin moment values.

Table S4. Experimental (X-ray) and DFT optimized bond lengths around the transition metal (Fe) centers of the diiron(III) complex in its HS-HS (S = 5) and HS-BS (S = 0). M1 = B3LYP/def2-SVP, M2 = B3LYP+D3BJ/def2-SVP+def2-TZVP, and M3 = BP86+D3BJ/def2-SVP+def2-TZVP). Bond lengths are given in Å.

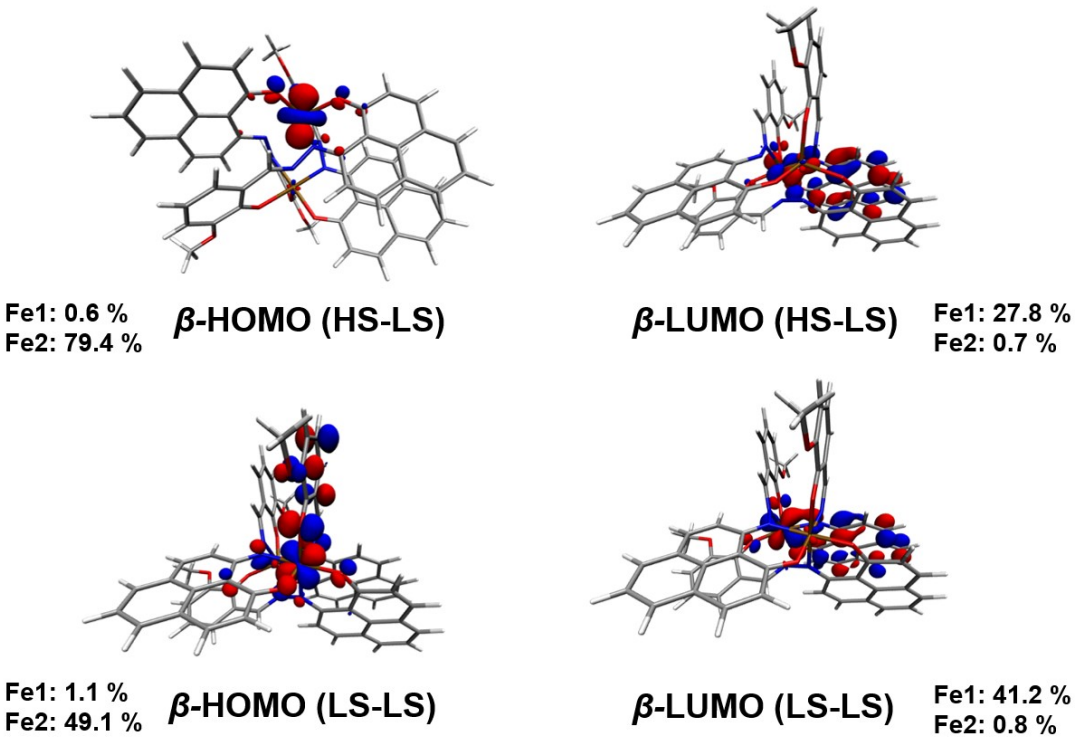

Figure S23. Molecular orbital plots of β-HOMO and β-LUMO orbitals of **1**$^{-1}$ complex in its LS-HS ($S = \frac{5}{2}$) and LS-LS ($S = \frac{1}{2}$) spin states . Molecular orbitals are generated at an isosurface value of 0.04 au. Compositions of metal ions are also given for each MO.

Theoretical computation of redox potential using DFT

The most popular method to compute the redox potential uses the Born-Haber cycle presented in Figure S24.

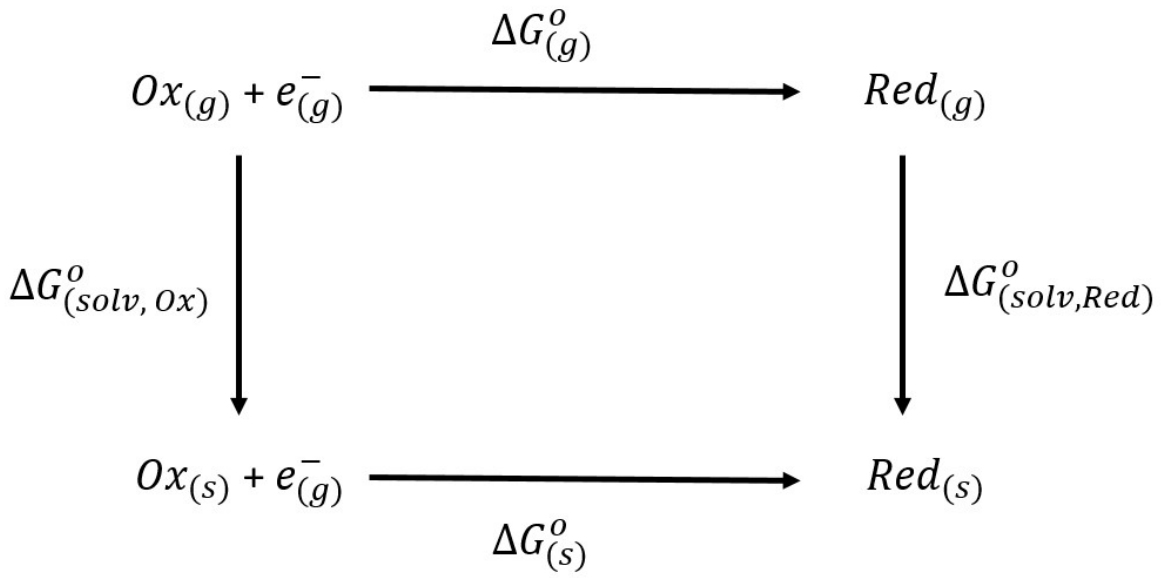

Figure S24. The Born-Haber cycle for redox potential calculation.

$\Delta G^{o}_{(g)}$ is the gas-phase Gibbs energy of the addition of one electron to the oxidant. It is a sum of the negative calculated electron affinity, and the thermal and entropic corrections. $\Delta G^{o}_{(solv,\,Ox)}$ and $\Delta G^{o}_{(solv,\,Red)}$ are solvation energy values of the oxidant and reductant molecule. This is achieved with the continuum solvation model CPCM. The entity $\Delta G^{o}_{(s)}$ is then calculated as:

$$\Delta G^{o}_{(s)} = \Delta G^{o}_{(g)} + \Delta G^{o}_{(solv,\,Red)} - \Delta G^{o}_{(solv,\,Ox)}$$

The absolute reduction potential E^{o}_{abs} of the Ox/Red couple in Solvent is defined as

$$E^{o\ (Solv)}_{abs} = -\frac{\Delta G^{o}_{(s)}}{nF},$$

where *n* is number of electrons involved in the half-reaction, present case *n* = 1. *F* is the Faraday constant (F = 96485 J. mol^{-1}.V^{-1} or 23.061 kcal/mol^{-1}.V^{-1}).
