ESI contains 6 figures (Figures S1-S5) and 3 tables (Table S1-S3).

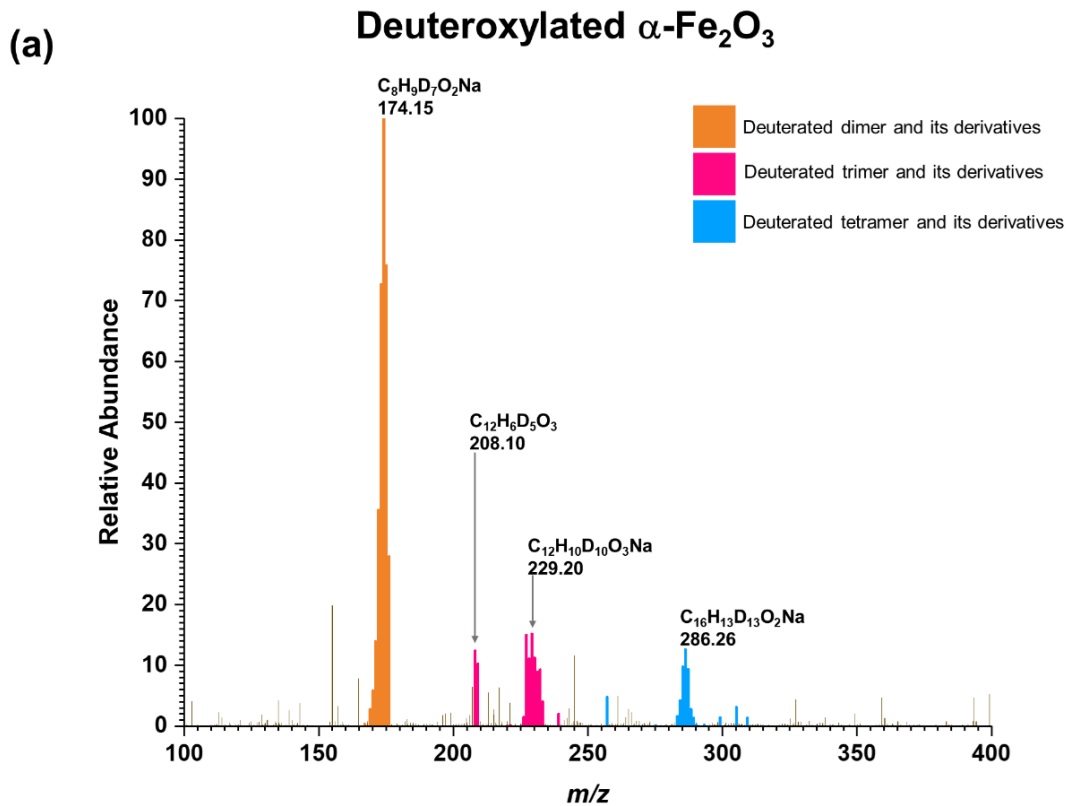

**Figure S1:** Gas-phase FTIR spectrum of Methyl Ethyl Ketone (MEK), 200 mTorr in the spectral region from 800 - 4000  $\text{cm}^{-1}$ . The peak at 3454  $\text{cm}^{-1}$  is assigned to C=O bond overtone, whereas the peak at 1738  $\text{cm}^{-1}$  is assigned to C=O bond stretching vibration. The peaks at 2992, 2959, 2950, 2941, and 2917  $\text{cm}^{-1}$  are assigned to various C-H stretching bond vibrations, and the peak at 1457, 1431 and 1371  $\text{cm}^{-1}$  are assigned to C-H bond bending vibrations. 1174  $\text{cm}^{-1}$  is assigned to C-C bond vibration. Peak assignments were based on existing literature assignments<sup>1</sup> and Computational Chemistry Calculations (phase: gas-phase, method:  $\omega$ B97X-D, basis set: 6-31G\*, package used: SPARTAN'20 Mechanics Program 20.1.4). Absorption scale is provided in the top left corner.

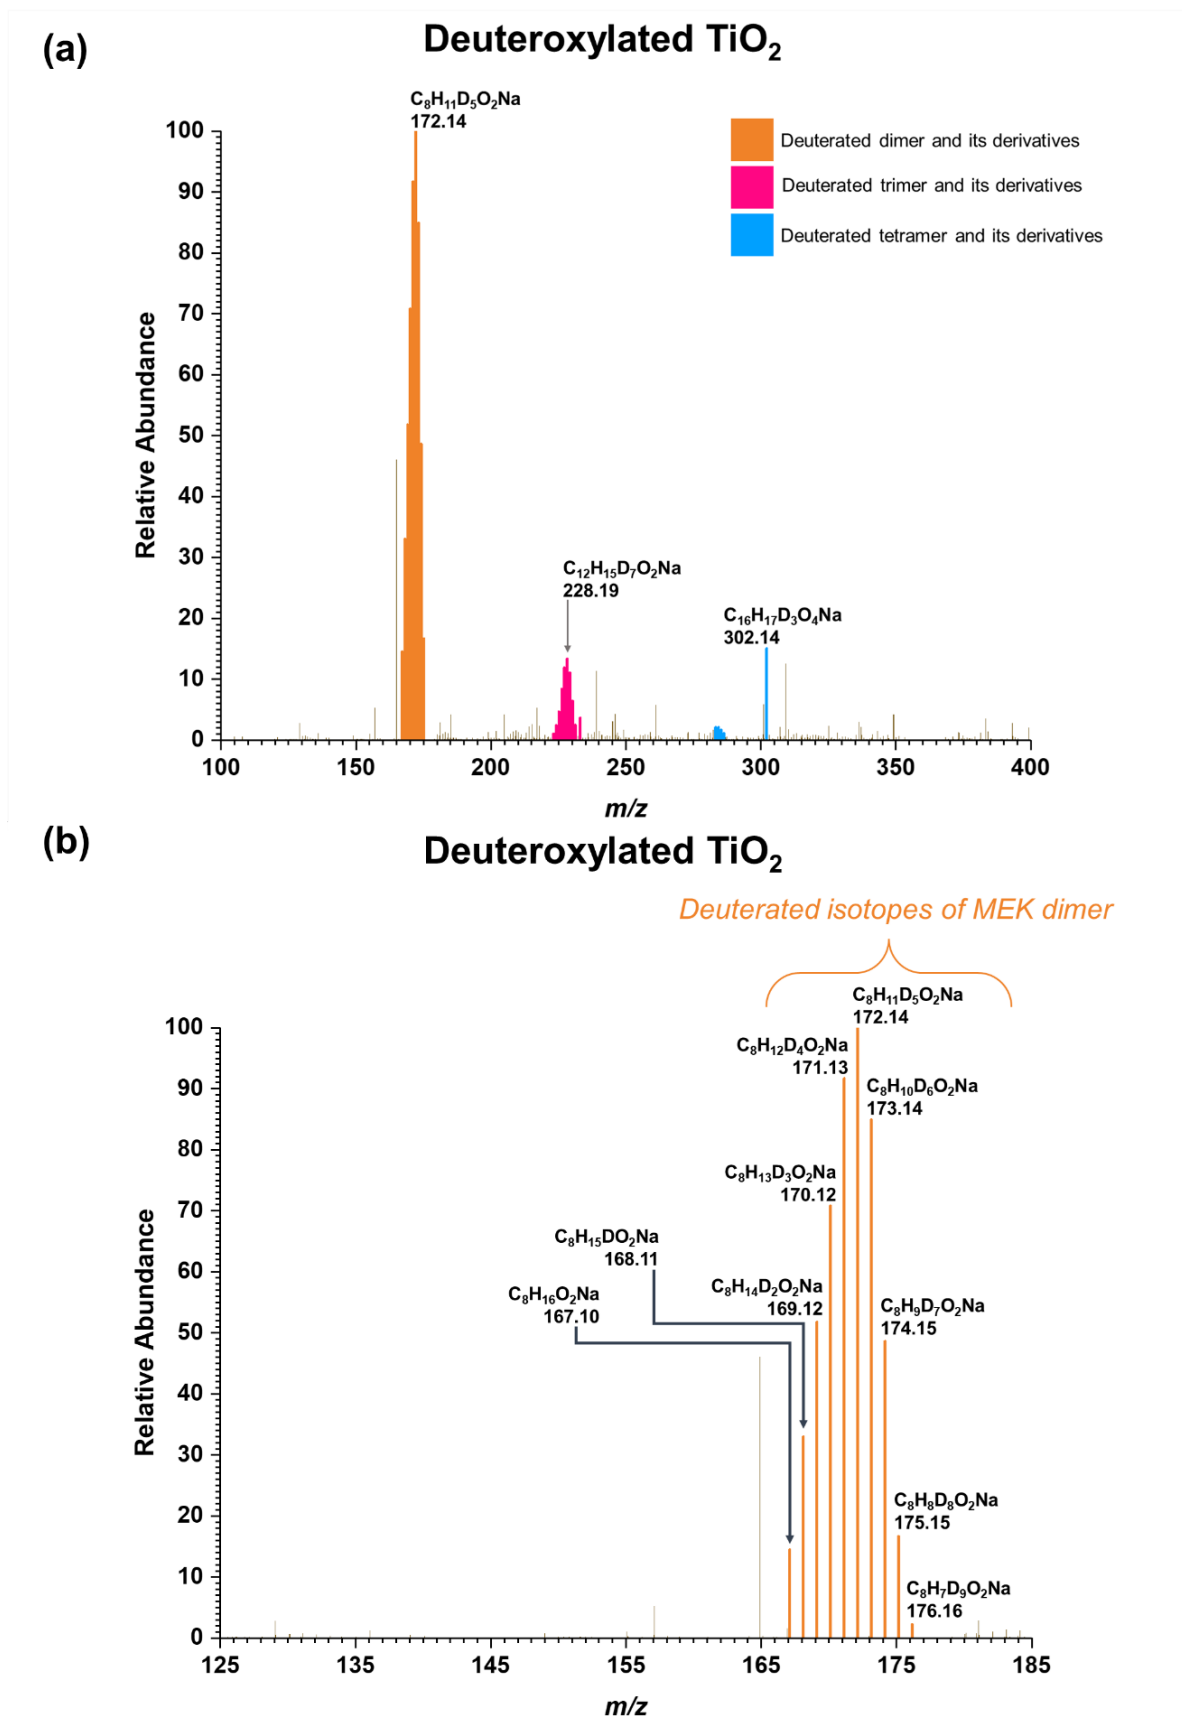

**Figure S2:** HRMS patterns of 70 ppm MEK standard in methanol. MEK remains as the sodated monomer during analysis. At very high MEK standard concentrations (1000 ppm), MEK forms a sodated dimer ( $m/z$  167.10). However, on mineral surfaces, even with lower pressures used, significantly larger intensities of a MEK dimer were observed indicating surface-driven dimerization. Importantly, MS/MS fragmentation of  $m/z = 167.10$  from MEK standard (1000 ppm) produced only one fragment at  $m/z = 95.05$  for MEK monomer, whereas for  $m/z = 167.10$  peak observed on mineral surfaces produced other fragments as shown in **Table S1**. This indicates that at higher concentrations, the standard MEK sample produced a clustered ‘dimer’ under MS conditions,<sup>2</sup> while on mineral surfaces, MEK produced a true dimer with the structure of compound **1**. Additionally, other oligomers observed on mineral surfaces were neither detected in 70 ppm nor 1000 ppm MEK standards in methanol. Moreover, no additional products were identified in MEK standard samples confirming that it doesn’t react with methanol at either solvent extraction or HRMS analysis steps.

**Figure S3:** FTIR spectra of adsorbed Methyl Ethyl Ketone (MEK), 100 mTorr (a) after 15 minutes of exposure on hydroxylated and deuterioxylyated  $\alpha\text{-Fe}_2\text{O}_3$  surfaces and (b) after evacuating overnight, in the spectral region from 1140 - 4000  $\text{cm}^{-1}$ . The absorbance scale is shown in the top left corner.

**Figure S4:** HRMS patterns of surface products formed upon adsorption on MEK on deuterated  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>. (a) Deuterated isotopes of and their dehydration products corresponding to MEK dimer, trimer, and tetramer. (b) Isotope variation of MEK dimer.

**Figure S5:** HRMS patterns of surface products formed upon adsorption on MEK on deuterated TiO<sub>2</sub>. (a) Deuterated isotopes of and their dehydration products corresponding to MEK dimer, trimer, and tetramer. (b) Isotope variation of MEK dimer.

# Arizona Test Dust

**Figure S6:** HRMS patterns of surface products formed upon adsorption on MEK on Arizona Test Dust (AZTD).

**Table S1:** MS/MS Analysis of Identified Compounds.
